# THE LANCET.

A Journal of British and Foreign Medicine, Surgery, Obstetrics, Physiology,  
Chemistry, Pharmacology, Public Health, and News.

IN TWO VOLUMES ANNUALLY.

VOL. CXCVI.

VOL. I. FOR 1919.

---

NINETY - SEVENTH YEAR.

---

SAMUEL SQUIRE SPRIGGE, M.A., M.D. CANTAB.,  
*EDITOR.*

---

LONDON

PRINTED AND PUBLISHED BY THE PROPRIETORS, AT THE OFFICES OF "THE LANCET," No. 423, STRAND, AND  
Nos 1 & 2, BEDFORD STREET, STRAND

MCMXIX.

# INDEX TO VOLUME I, 1919.

 Readers in search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as *Brain and Cerebral*, *Heart and Cardiac*, *Liver and Hepatic*, *Bicycle and Cycle*, *Child and Infant*, *Bronchocele*, *Goitre*, and *Thyroid*, *Diabetes*, *Glycosuria* and *Sugar*, *Eye*, *Ophthalmic*, and *Vision*, &c., &c. (Py Q) = Parliamentary Question.

### A

Aberhalden's pregnancy reaction, 111  
Abdominal operation, hæmatemesis after, 529;  
reflexes, significance and surgical value of  
(Mr. D. Ligat), 729; tuberculosis, 940  
Aberdeen Royal Infirmary, meeting, 414  
Aberdeen University, pass lists, 87, 584; spring  
graduation, 584; Prof. C. R. Marshall  
appointed to the Regius chair of materia  
medica and therapeutics, 854; club dinner,  
582  
Abiotrophy of the retinal neuro epithelium or  
"retinitis pigmentosa," 893  
Abortifacient, quinine as (Prof. W. C. Swayne  
and Mr. E. Russell), 841  
Abrahams, Dr. A., Dr. N. Hallows, and Dr. H.  
French, influenza septicæmia, 1  
Abrahams, Maj. A., epidemic perinephric sup-  
puration, 1044  
Abscess in fibromyoma, 22; pyosalpinx and  
ovarian, 265  
Abscess, peritonsillar (Dr. A. Wylie), 178  
Abscesses, fixation in influenza, 895  
Absentee, practice of the, 45, 80  
Accommodation for hospital nurses (Py Q), 770  
Acetone, alcohol, and benzene in the air of  
certain factories, 772  
Achard, Prof. C., Review of Studies on Renal  
Function in Chronic Nephritis (thesis by  
Pasteur-Vallery-Radot), 752  
Acidosis and its significance, 30  
Ackerley, Dr. R., "hot liquids and cancer,"  
635  
Adami, Prof. J. G., prevention and arrest of  
venereal disease in the Army, 109; War Story  
of the Canadian Army Medical Corps  
(review), 111  
Adams, Dr. D. K., acute ascending myelitis,  
482  
Adams, Mr. J., new pattern gland dissector,  
868  
Adams, Mr. J. E., maldevelopment of the  
liver, 744; carcinoma of appendix, 845  
Adamson, Dr. Rhoda, effect of industrial  
employment upon women, 465  
Adenoids, treatment of, 284, 323  
Advanced Suggestion (Neuro-induction) (Mr.  
H. Brown) (review), 302  
After-care of tuberculous ex-service men, 767  
Agglutination test, standard, permanent  
criterion for (Mr. A. D. Gardner), 21  
Agglutinins, other, formation of, in cases of  
Malta fever (Dr. L. T. Burra), 64  
Aids to Medical Diagnosis (Dr. A. Whiting),  
second edition, 1918 (review), 112; to Sur-  
gery (Dr. J. Cunningham and Mr. C. A. Joll),  
fourth edition, 1919 (review), 659; to the  
Analysis of Foods and Drugs (Mr. C. G.  
Moor and Mr. W. Partridge), fourth edition,  
1918 (review), 848; to Histology (Dr. A.  
Goodall), second edition (review), 848  
Air for oxygen in anaesthesia (Dr. J. H. Fryer),  
216  
Aitken, Capt. R., R.A.M.C. (see Obituary of  
the war)

Aitken, Dr. C. J. H., invalidism for 15 years  
through nasal blockage, 156  
Albert medal, award, 915  
Alberta Health Department, 232  
Aldridge, Dr. C., death of, 843  
Alexander, Dr. W., obituary, 530  
Allahabad, new medical school, 760  
Allbutt, Sir C., portrait of, 814, 910  
Allen, Capt. W. R., R.A.M.C. (see Obituary of  
the war)  
Allotments and health, 284  
Alport, Capt. A. C., Malaria and its Treatment,  
in the Line and at the Base (review), 616  
Amar, Prof. J., Physiology of Industrial  
Organisation (review), 265  
Ambiasine, 898  
Ambulances, Red Cross, utilisation of, 187  
America, visit of foreign medical men, 1091  
American Journal of Care for Cripples (review),  
426  
American Journal of Ophthalmology (review),  
1029  
American Journal of Public Health (review),  
660  
American Medical Corps, work of, 431  
American Public Health Association and  
influenza, 230; gifts, 318; post-graduates in  
London, 943  
American Review of Tuberculosis (review), 265,  
468, 566, 747, 1029  
Amoebic and bacillary dysentery, diagnosis of  
(Dr. G. M. Findlay), 135; dysentery carriers,  
a correction, 157; dysentery, treatment, 429;  
dysentery, 674  
Anamia, severe, 700; aplastic, 744; jaundice  
in (Dr. W. H. Willcox), 932  
Anaerobic tube, Buchner's, modified, 226  
Anaesthesia, spinal (Dr. F. S. Rood), 14; air for  
oxygen in (Dr. J. H. Fryer), 216; safe, 231;  
surgical, lacrymal gland in (Dr. L. T. Ruther-  
ford), 792; rectal ether (Mr. J. C. Clayton),  
793; for ophthalmic operations (Mr. C. T. W.  
Hirsch), 1068  
Anæsthetics, a nasal air-way, 1030; Dr. J.  
Regnault on, 1037

### ANALYTICAL RECORDS FROM "THE LANCET"

#### LABORATORY—

Ambiasine, 898  
Aniodol, 384  
"Colectant" lozenges, 24  
Digalen, 384  
Ethyl chloride films, 24  
Feroxal, 24  
Genasprin, 24  
Influenza vaccine (mixed), 24  
Italian ichthyol, 24  
Omnopon, 384  
Petroleum jellies ("Semprolia" brand), 898  
Sedobrol, 384  
Solution pot. iodide (Souffron), 384  
Strophanthus and strophanthine (cris-  
tallisé), 384  
Thiocol, 384  
Valenda spray, 898  
Veronidia, 24

Anaphylaxis (Dr. J. K. Gaunt), 889  
Anatomical films, 1125  
Anatomy, chair of, University College, London,  
989  
Anderson, Dr. H. G., Medical and Surgical  
Aspects of Aviation (review), 982  
Anderson, Mr. W. H., dislocation of teeth, 441  
Andrews, Dr. H. R., four cases of full-time  
ectopic pregnancy, 611; removal of sub-  
mucous fibroid with Hegar's dilators, 1073  
Aneurysm, traumatic, of external carotid  
(Dr. S. C. Dyke), 21; aortic, 700; cirroid,  
700  
Angeloid streak in retina, 613  
Angioma of retina, 300; of the choroid, 895  
Animal ailments in 1918, 1088  
Animal Life and Human Progress (Prof. A.  
Dendy) (review), 1120  
Animals (Anæsthetics) Bill, 821  
Aniodol, 384  
Ankylostomiasis, oil of chenopodium in, 90;  
in Australia, 476  
Annals of Medical History (review), 566  
Anthrax, appointment of Advisory Committee,  
200; prevention of, 821  
Anthrax Bill, Prevention of, 685, 865, 969  
Anti-hookworm campaign in tea districts, 998  
Antimony in bilharziasis, 79; tartrate for  
bilharziasis (Dr. J. B. Christopherson),  
1021  
Antiplague serum in influenza, 663  
Antipyrin, persistent pigmentation due to,  
1036  
Antirabic treatment (Py Q), 918; centres,  
1138  
Aortic aneurysm, 700  
Aplastic anæmia, 744  
Apothecaries' assistants, qualifications of  
(Py Q), 442  
Apothecaries Society of London, pass-lists,  
43, 584  
Apparatus, new "606," 618  
Appendicitis, acute, and acute appendicular  
obstruction (Mr. S. T. Irwin), 98, 197;  
accurate diagnosis in (leading article), 114,  
197; X rays in diagnosis, 279; coexistence of  
small gut reflex in cases of (Mr. D. Ligat),  
731; acute (Dr. R. A. Barlow), 844  
Appendix, vermiform, examination by X rays  
(Dr. E. I. Spriggs), 91; carcinoma of, 845  
Apperly, Mr. R. E., heart failure, 658  
Appointments, weekly lists of, 49, 89, 127, 162,  
200, 240, 321, 362, 405, 445, 487, 537, 589, 642,  
726, 824, 865, 919, 961, 1009, 1061, 1096, 1138  
Apprexial symptoms of malaria, 222  
"Arellano" influenza mask, 90  
Armour, Col. D., cirroid aneurysm, 700  
Army huts for tuberculous patients (Py Q),  
641; medical equipment, surplus (Py Q), 864  
Arthritis and rheumatism, meningococcal (Dr.  
P. Sainton), 1080  
Artificial limbs (Py Q), 320, 321  
Ascending paralysis, acute (Dr. H. Sutherland),  
841  
Ashe, Dr. J. S., endothelioma of the ovary, 264  
Aspirin, intolerance of (Dr. E. J. Tyrrell), 1118  
Aspirin poisoning (Dr. F. W. Lewis), 64

- Assessments, disability, and medical boards (Py Q), 918
- Association of Factory Doctors and Managers, 768
- Association of Panel Committees and notification fees, 439
- Association of Public Vaccinators, meeting, 443
- Astley Cooper prize, 282
- Astrialgus, fracture-dislocation of (Mr. H. C. Orrin), 20
- Asylum Workers' Association, meeting, 955
- Atmospheric pollution, monthly record, 81; Meteorological Office Advisory Committee on, report on observations in the year 1917-1918 (see Supplement, June 14th); investigation of, 1035
- AUSTRALIA, CORRESPONDENCE FROM—Influenza pandemic; Influenza vaccines; Nationalisation of medicine; Ankylostomiasis; Australian Army Medical Corps, 476—Influenza epidemic; Inoculation and masks; Unseemly disputes, 681—Influenza; Federal and State quarantine, 760
- Australian Army Medical Corps in Egypt in 1914-15 (Sir J. W. Barrett and Lieut. P. E. Deane) (review), 66
- Autonomic nervous system, arrangement of, 951
- Autotherapy or bleeding, 124
- Autumn influenza epidemic (1918) (Dr. J. W. H. Eyre and Dr. E. C. Lowe), 553
- Aviation candidates, medical examination of, 46 Insurance Association, 435
- Aviation, medical aspects of (Dr. L. E. Stamm), 206; Medical and Surgical Aspects of (Dr. H. G. Anderson) (review), 982
- Aviators, nasal obstruction in (Dr. D. Guthrie), 136; visual requirements of, 894
- B
- Babies in Peril, or Mother and Infant Welfare Centres (Miss E. M. Bennett) (review), 618
- Bacillary dysentery: are relapses frequent, 529; dysentery, 673; dysentery, mild (Dr. J. Kyle), 937
- Bacilli, tubercle, human, bovine, and avian, attenuation of (Dr. N. Raw), 376
- Bacillus influenzae*, simply prepared culture-media for (Mr. A. Fleming), 138
- Bacillus multifermentans lenidus* (Dr. J. L. Stoddard), 13
- B. paratyphosus B*, an atypical strain of (Dr. W. Broughton-Alcock), 1023
- Bacteriology, Manual of (Prof. R. Muir and Prof. J. Ritchie), seventh edition, 1919 (review), 467; endowed chair, 988
- Bacteriology of influenza, 760; epidemic in Lower Egypt (Dr. G. M. Findlay), 1113
- Bailey, Capt. J. C. M., R.A.M.C., O.B.E. (see Obituary of the war)
- Baillie, Dr. D. M., use of intravenous iodine in influenza broncho-pneumonia, 423; and Mr. E. G. D. Pineo, treatment of gonorrhœa by pus vaccines, 508
- Baines, Mr. A. E., Studies in Electro-physiology (Animal and Vegetable) (review), 701
- Baldwin, Mr. A., plastic operation on face for deep scarring, 360
- Balfour, Dr. A., sanitary and insanitary make-shifts in the Eastern war areas, 604
- Balgarnie, Dr. W., ruptured rectus abdominis, influenza, 843
- Ballance, Sir C., and Dr. H. Campbell, general paralysis of the insane, treatment, 668
- Barber, Dr. H., Dr. C. F. White, and Dr. A. T. McWhirter, Wassermann reaction, a criticism of its reliability, 502
- Bardswell, Dr. N. D., Y.M.C.A. Agricultural Training Colony, Kinross, Dorset, 456; public health aspect of tuberculosis, 464
- Barium salts administered for radiological examination, death from, 943
- Barlow, Dr. R. A., acute appendicitis, 844
- Baron, Sir B. J., death of, 1035
- Barrett, Lady, deficiency of the pituitary body in a girl, 465
- Barrett, Sir J. W., and Lieut. P. E. Deane, Australian Army Medical Corps in Egypt in 1914-15 (review), 66; management of venereal diseases in Egypt during the war, 140, 193
- Barton, Mr. E. A., quality of commercial vaccine lymph, 313
- Bashford, Capt. R. F., Capt. J. A. Wilson, and Maj.-Gen. Sir J. R. Bradford, filter-passing virus in certain diseases, 169; acute infective polyneuritis, 348
- Bassett, Lieut. R. J., R.A.M.C. (see Obituary of the war)
- Bassett-Smith, Surg. Capt. P. W., sprue associated with tetany, 178
- Bastian, Surg.-Com. W., origin of life, work of the late Charlton Bastian, 951
- Basu, Maj. B. D., Diabetes and its Dietetic Treatment, ninth edition, 1918 (review), 353
- Bateman, Dr. A. G., death of, 679
- Bath, the new, 1037
- Batten, Mr. H., disease of both maculae, 613
- Baule, Dr. P., Dr. R. Coope, and Dr. E. Joltrain, chronic colopathies, 933
- Baylis, Mr. H. A., Incidence of *Entamoeba histolytica*, &c., in naval entrants, 54; amoebic dysentery carriers, a correction, 157
- Bayliss, Prof. W. M., wound shock, 663; and Dr. H. H. Dale, shock, discussion, 256
- Bayly, Mr. H. W., laboratory methods and diagnosis of venereal diseases, 817
- Beattie, Prof. J. M., diagnostic value of the Wassermann reaction in syphilis, 466
- Bed for fractures and general hospital purposes, 266
- Bedside and Wheel-chair Occupations (Dr. H. J. Hall) (review), 800
- Begg, Col. C. M., C.B., C.M.G., New Zealand M.C. (see Obituary of the war)
- Belfast, health of, 121; strike in, 193; Hospital for Skin Diseases, meeting, 193; Royal Victoria Hospital, resignation of Sir W. Whittle, M.P., as senior physician, 274; Queen's University, Col. T. Sinclair elected registrar, 358; doctors and Ministry of Health, 577; Ophthalmic Hospital, meeting, 997; Dental Clinic, 1040
- Belgian Doctors' and Pharmacists' Relief Fund, 37, 125, 384, 618; (leading article), 228; close of the fund, 235; decorations, 915
- Bell, Dr. B., abscess in fibromyoma, 22
- Bell, Mr. A. S. G., cerebro-spinal meningitis, 887
- Benaroya, Dr. M., lung-puncture in treatment of influenza pneumonia, 742
- Benn Ulster Eye, Ear, and Throat Hospital, Belfast, meeting, 722
- Bennett, Miss E. M., Babies in Peril, or Mother and Infant Welfare Centres (review), 618
- Bennett, Mr. L. H., obituary, 125
- Bennett, Dr. R. A., intestinal obstruction by Meckel's diverticulum, 1117
- Benson, Mr. C. M., obituary, 358
- Berkeley, Dr. C., Gynecology for Nurses and Gynecological Nursing, third edition, 1918 (review), 848
- Bertrand, Mlle. T., and M. Emile Sergeant, meningeal hemorrhage in typhoid fever, 519
- Bilharziasis (Dr. N. H. Fairley), 1016; its prevention and treatment (leading article), 1032
- Bilharziasis, antimony in, 79; antimony tartrate for (Dr. J. B. Christopherson), 1021
- "Billie Carleton," inquest on, 236
- Bing, Prof. R., and Dr. A. L. Vischer, psychology of internment, 697
- Bingham, Capt. J. W., R.A.M.C. (see Obituary of the war)
- Biochemistry and Physiology in Modern Medicine (Prof. J. J. R. Macleod and Dr. R. G. Pearce) (review), 513
- Biological Chemistry, Study of (Dr. S. B. Schryver) (review), 659
- Biology and the medical curriculum (Mr. T. G. Hill), 273, 312
- Biology, Experimental, Monographs on, the Elementary Nervous System (Prof. A. H. Parker) (review), 702
- Bird's brain, the, 616
- Birmingham University, post-graduate study, 725
- Births, marriages, and deaths, weekly lists of, 49, 89, 127, 162, 200, 240, 283, 322, 362, 404, 445, 487, 537, 590, 642, 686, 726, 771, 825, 866, 919, 962, 1009, 1052, 1097, 1138
- "Birthplace of gynecology," 189
- Bismuth Orfer, the, 128
- Black, Dr. Guy, the late, 1003
- Blackwater fever (Mr. J. P. Williams), 886
- Blake, Lieut. Col. J. A., Gunshot Fractures of Extremities (review), 184; Fractures (Gunshot Fractures of Extremities) (review), 702
- Blackway, Mr. H., obituary, 358
- Blanchard, Prof. R., obituary, 315
- Bland-Sutton, Sir J., glizzards and counterfeit glizzards, 203; missiles as emboli, 773
- Bleeding or autothorapy, 124
- Blind men on committees, 868; subject, the case of, 964; in Ireland, treatment of (Py Q), 1051
- Blood, diseases of, transfusion in, 379; volume and related blood changes in hemorrhage, 852; transfusion by the citrate method (Mr. A. Fleming and Dr. A. B. Porteous), 973, 988; transfusion (Dr. E. L. Hunt and Dr. Helen Inglety), 975, 988; transfusion, Pepsin on, 1093
- Blood-supply of muscles (Dr. J. Campbell and Dr. C. M. Pennefather), 294
- Board of Customs, medical office: to (Py Q), 1009
- Boards of guardians, powers of (Py Q), 918
- Bock, Airlie V., and O. H. Robertson, blood volume and related blood changes after hemorrhage, 852
- Bodily Deformities (Mr. E. J. Chance) (review), 800
- Body temperature, electrical methods of measuring, 564
- Boerhaave, Hermann, 576
- Boisseau, J., G. Roussy, and M. D'Oelsnitz, Traitement des Psychonévroses de Guerre (review), 1119
- Bolduan, Dr. C. F., and Dr. J. Koopman, Immune Sera, fifth edition, 1917 (review), 746
- Bone grafts, mandibular, 181; sinuses, treatment by solid metal drains (Mr. C. J. Symonds), 971
- Bone-grafting operations (Mr. W. M. Munby and Mr. A. D. E. Shefford), 1070
- Bonney, Mr. V., continued high maternal mortality of childbearing, 775, 796
- Bonus to nurses in South Africa, 1026
- Books, &c., received, 87, 162, 241, 324, 406, 486, 540, 771, 825, 866, 920, 962, 1010, 1096
- Books of reference, 324; for Serbia, 398, 643; in large libraries, care of, 826
- Booth, Dr. J. M., obituary, 860
- Borland, Dr. V., prophylactic treatment of constipation in children, 459

## Obstetric helper, 797

Obstetrics and gynecology, teaching of, to medical students, discussion, 258  
Occupational fractures, 349  
Odes and Other Poems (Dr. R. C. Macfie) (review), 1119  
Oesophagus, malignant stricture of, 303  
Ogilvie, Dr. G., obituary, 44  
Oil of chenopodium in ankyllostomiasis, 90

Oils and Fats, Edible (Mr. C. A. Mitchell) (review), 843; Fats, and Waxes, Technical Handbook (Mr. P. J. Fryer and Mr. F. E. Weston) (review), 897  
O'Keefe, Capt. W. R., R.A.M.C. (see Obituary of the war)  
O'Malley, Mr. J. F., circumscribed labyrinthitis, 893  
Omnipon, 384  
One-eyed man, the, 1085  
Oswlow, Mr. H., origin of life, work of the late Cha. Iton Bastian, 1001  
Ontario Medical Association, address in medicine, 1132  
Operations, 530 consecutive, at Mercer's Hospital, 265; nerve and muscle during, faradic stimulation of (Mr. H. Platt and Mr. E. S. Brentnall), 884  
Ophthalmia neonatorum, notification of, 948  
Ophthalmic cases, 8670, analysis of, 473; operations, anaesthesia for (Mr. C. T. W. Hirsch), 168  
Ophthalmic practice, panel (Dr. A. F. Fergus), 758  
Ophthalmitis, sympathetic, with fundus changes, 300  
Ophthalmological Society of the United Kingdom, Congress (see Medical Societies)  
Ophthalmology, education in, report, 578  
Ophthalmology, Medical (Dr. A. Knapp) (review), 23  
Ophthalmoscope, familiarity with, 232  
Opium Convention of 1912 (Py Q), 443, 726  
Optic nerve, evulsion of, 895  
Optical Goods Industry, Employment Opportunities for Handicapped Men (Mr. B. J. Morris) (review), 982  
Orbit and accessory sinuses, injuries and diseases of, 614, 699  
Orbital region, plastic operation on, 894  
Organic Chemistry, Recent Advances in (Mr. W. Stewart), third edition, 1918 (review), 617  
Organs of Internal Secretion, their Diseases and Therapeutic Application (Dr. I. G. Cebbi), second edition, 1918 (review), 111  
Ormond, Maj. A. W., analysis of 8670 ophthalmic cases, 473; pituitary tumour, 613  
Orin, Mr. H. C., fracture-dislocation of astragalus, 20  
Orthopaedic surgery, physical treatment in relation to, 671; conference in Liverpool, 1003  
Orthopaedic Treatment of Gunshot Injuries (Dr. L. Mayer) (review), 23; Effects of Gunshot Wounds and their After Treatment (Dr. S. W. Daw) (review), 847  
Osler, Sir W., influenza pneumonia, 501; acute pneumonic tuberculosis, 615; re-stocking of Louvain Library, 1042; presentation to, 1128; anniversary book, 1138  
Osteo-arthritis in right hip joint, 447, 488, 592  
Osteomyelitis, Traumatic, Chronic, its Pathology and Treatment (Dr. J. R. White) (review), 1074  
Osteopathy, 949  
Ostitis, new method of incision of tympanic membrane for (Mr. R. Lake), 977  
Otate, Dr. S., Science and Art of Deep Breathing (review), 467  
Otitis, chronic adhesive, 893  
"Ourselves only," 858, 913, 951  
Outlook of the medical practitioner (leading article), 145  
Outlook, the (leading article), 1121  
Out-of-school employment, 907  
Ovarian cyst, spontaneous rupture (Dr. D. N. Kalyanvala), 423  
Ovary, endometrioma of, 264  
Overy, Dr. H. B., causes and incidence of dental caries, 47  
Owen, Dr. S. A., and Dr. P. A. Leighton, medullary symptom-complex, 1024, 1037  
Oxford Ophthalmological Congress, 443, 1135  
Oxygen in anaesthesia, air for (Dr. J. H. Fryer), 216

## P

Page, Mr. C. M., Medical Field Service Book (review), 383  
Paine, Dr. S. G., origin of life, work of the late Charlton Bastian, 1092  
Paisseau, G., malaria during the war, 749  
Palmar fascia, unusual contracture of (Dr. G. de Swietochowski), 238  
Palmer, Mr. J. F., hypothermia in influenza, 398  
Pancreatitis a cause of enteralgia (Dr. L. Brown), 876  
Panel practice, the size of (Py Q), 403; ophthalmic practice (Dr. A. F. Fergus), 758  
Panel practitioners, war bonus to (Py Q), 321, 401, 405; releasing (Py Q), 403; practitioners and tuberculosis officers, 895; Committee, London, meeting, 855; practitioners' remuneration (Py Q), 959

# The Goulstonian Lectures

ON

## THE SPREAD OF BACTERIAL INFECTION.

*Delivered before the Royal College of Physicians of London*

By W. W. C. TOPLEY, M.A., M.D. CANTAB., F.R.C.P.,  
DIRECTOR OF INSTITUTE OF PATHOLOGY, CHARING CROSS HOSPITAL.

### LECTURE I.

[IN ABRIDGED FORM.]

MR. PRESIDENT, LADIES, AND GENTLEMEN,—It is my first and most pleasant duty to return thanks for the honour of selection as Goulstonian lecturer. It is common with lecturers to claim indulgence, but I fear that in my own case the plea is unusually necessary. If the experimental part of the evidence which I lay before you is incomplete, and in cases fragmentary, I would ask you to remember that the circumstances of the past year have rendered research work of any kind far from easy.

In selecting a subject for such lectures as these one's thoughts naturally turn to those aspects of medical work which have recently impressed themselves most forcibly on the attention. While serving under Colonel Hunter in Serbia during 1915 it was my lot to be witness what was, I suppose, when considered in all its aspects, one of the most terrible epidemics of recent times. Since my return to work at my own hospital the routine examinations in the laboratory, especially in connexion with the military wards, have kept constantly before us the bacteriological aspects of preventive medicine as applied to war conditions. It seemed, therefore, not unnatural to attempt to bring together such data as we possess with regard to the spread, and especially the epidemic spread, of bacterial infection; and to supplement it, if possible, by experimental inquiry in the hope that the result might be of interest to others, and the certainty that the exercise would at least be of benefit to myself.

#### THE WAYS OF APPROACHING THE QUESTION.

The subject under discussion may be approached from at least three sides, the epidemiological, the bacteriological, and the biometrical. The first and third may perhaps be regarded as identical, but the statistics of the epidemiologist, who is concerned mainly with the historical and geographical aspects of his subject, differ so widely from those mathematical methods more recently evolved that biometrics has developed a technique which it seems better to regard as belonging to a separate branch of biological science. While it is with the bacteriological aspect of the question that I am here mainly concerned, yet it is impossible to consider one side of the problem alone without losing all sense of proportion.

#### *The Epidemiological Aspect.*

If we survey the results hitherto obtained in the epidemiological and bacteriological fields we note at once that the two lines of inquiry tend to emphasise two different aspects of the phenomena observed. The epidemiologist puts before us a picture of certain diseases, varying often in their less important details, but showing a remarkable conformity to type when the whole aggregate of manifestations is considered, which arise for some unaccountable reason and attack a larger or smaller portion of the population living at the time. After causing ravages of greater or less extent they seem to disappear again only to reappear after a longer or shorter interval, and again run their course. Moreover, each successive visitation bears a striking resemblance to its predecessor, though the total number of cases, the total mortality in any one centre of population, and the distribution of the epidemic over the inhabited parts of the earth, vary greatly from one outbreak to another.

Thus epidemiology tends to lay stress on the constancy of a disease, as some process which continues through long ages of history, now rising to a climax, now relapsing into insignificance, but remaining a constantly menacing factor among the mass of circumstances that constitute the environment of our species. Thus it is possible to trace some of our epidemic diseases back into the dark ages of medical history,

and though we have only to go back a little way, as regards historical time (to say nothing of time as it is regarded by the biologist or geologist), to find the way confused and the shapes before us vague and doubtful, yet we can trace likenesses that leave us in little doubt that most of the enemies with whom we are now engaged have troubled our fathers before us.

#### *Bacteriological Lines of Inquiry.*

When we turn to the bacteriological aspect of the question we find a very different picture. Workers in this field have been more concerned with the minute investigation of comparatively small samples of cases than with the broad view of an epidemic of disease as a biological process. By these investigations they have been able to identify the causal organism of certain of the more important communicable diseases, and in recent years have brought forward data of the greatest importance for a better understanding of the factors involved in the spread of such infections. The foundations of bacteriology, indeed, rest on Pasteur's observations on the nature and prevention of infections characterised by their ready spread.

Rapid advance in the investigation of epidemic disease along bacteriological lines has, however, been so far prevented by two outstanding difficulties. The very diseases which would afford the most favourable field for study are just those in which the causal organisms are unknown. Scarlet fever, measles, small-pox, and chicken-pox, to mention only a few of the more outstanding examples, still await a satisfactory elucidation from this point of view. We have lost faith in one of our supposed causal organisms during the world-wide influenza epidemic which is still with us, and already there are many claimants to the vacant place, but no one of them has yet established its position.

The other great obstacle we have to face is our inability to convey to laboratory animals diseases as they occur in man. We can produce lesions of a definite and specific nature in the majority of cases, but not the actual disease in all its features, and among the features most frequently lost is that tendency to spread of infection which we should specially desire to study.

In spite of these limitations much has already been accomplished, and though much remains to be done there is little doubt that we are steadily gaining that knowledge which, if properly applied, will enable us to deal effectively with the great problem of infective diseases.

In any attempt to form a bacteriological conception of the processes involved in the epidemic spread of infection the ascertained facts of epidemiology must be kept constantly in mind.

#### THE MAIN PROBLEMS.

We may commence by asking ourselves what are the main problems to be solved and the most striking phenomena to be accounted for, assuming, as we have, I think, the right to do, that the organisms which the best bacteriological opinion regards as having established their causative rôle, do indeed play that part in the diseases in question, and that in other cases we are dealing with an unknown cause of essentially similar nature.

Considering the general picture presented by the historical and geographical data concerning any one of these diseases which have from time to time assumed an epidemic form, the questions that force themselves most prominently before us are probably the following:—

(1) Since the outbreaks are separated from one another by intervals of time, during which there may be a complete absence of the disease in its classical form, it is necessary to explain how and why the specific virus remains dormant for periods often extending over many years.

(2) If we can obtain a reasonably complete answer to this preliminary question, there remains the problem of why it is that the dormant virus periodically awakens to activity and gives rise to those outbreaks of disease which, in their pandemic or epidemic forms, show such strikingly constant characteristics. In seeking an answer to this question it will be necessary to include as facts to be explained those well-known preliminary phenomena which so often precede the appearance of an epidemic.

(3) If it be possible to form some reasonable conception of the causes which originate an epidemic it will still be necessary to show that such causes, operating further, will tend to produce the phenomena which are to be observed in the rise and subsequent subsidence of the wave of disease.

Any tenable theory must thus explain the constant presence of a specific cause of disease through long periods of time, the periodic reappearance of the disease in epidemic form and the characteristic form of each such wave of disease in its rise, crest, and subsidence, leading to another disease-free period.

#### THE HUMAN CARRIER.

The gradual accumulation of evidence pointing to the importance of the human carrier as a factor in the persistence of a bacterial virus during inter-epidemic periods has profoundly altered our conception on these matters. In how far persistence in soil, water, or other inanimate habitats may contribute to the preservation of pathogenic bacterial species, we have no certain knowledge; nor have we in most cases adequate data on the prolonged existence in other animal hosts of bacteria potentially pathogenic for man—a factor which is probably of far greater importance. The fact which has been brought into prominence, and which has been more and more clearly established as a general law, is the continued parasitic existence in man of bacteria known to be capable of causing disease, without the actual production of the disease in question.

The extensive studies which have been carried out in connexion with the carrier problem have yielded data of the greatest value concerning the relative distribution of such parasites at epidemic as contrasted with non-epidemic times, and especially in epidemic as contrasted with non-epidemic areas. The position as it stood in 1912 is admirably summarised in Ledingham and Arkwright's "Carrier Problem in Infectious Diseases." Very thorough investigations have been carried out during the past four years in connexion with those epidemic diseases which have assumed special importance under war conditions, and the results, as set forth in various reports to the Medical Research Committee, to the Local Government Board, and in other papers, afford data of the highest significance.

Without considering in detail the bacteriological evidence in connexion with each of those epidemic diseases in which knowledge of the causative parasite enables us to pursue an inquiry along these lines, we may summarise the relevant facts which have come to light, sometimes in one disease, sometimes in another, but which are being more and more surely established as general principles by the gradual accumulation of evidence.

#### SUMMARY OF PRESENT KNOWLEDGE.

It seems to be a general law that, where a given bacterial infection is associated with the presence of the causative parasite in certain excretions or on certain mucous surfaces, the tendency is for the organism to persist in such situations for a certain short interval, usually a few weeks, and then to disappear. In some cases, however, it persists over much longer periods, sometimes, as in certain typhoid carriers, for 25 years or more. These chronic carriers form a relatively small proportion of the persons infected, and in many cases there is a well-defined association between the carrier-state and some other pathological condition in the host. Thus typhoid carriers are especially common among those persons who are suffering from lesions of the gall-bladder, and hence the condition occurs more frequently in women than in men. Similarly the presence of enlarged and unhealthy tonsils would appear to contribute to the persistent carrying of the *B. diphtheriae*.

In the case of many bacterial parasites there is ample evidence that pathogenic species are distributed fairly widely throughout the general population, and it seems probable that, if any large sample of the community could be minutely investigated, most of those bacteria, which are recognised to be the cause of the epidemic diseases natural to the locality concerned, would be detected in one or more of the individuals examined.

#### Carrier-rates among Contacts and Non-contacts.

If such an inquiry be carried out in an area in which an epidemic is actually occurring it will be found that a proportion of individuals, in apparently perfect health but who have been in more or less intimate contact with cases of the disease in question, are harbouring the specific parasite. Moreover, the percentage of such carriers among healthy contacts will be considerably higher than among the general non-contact population. Thus Graham-Smith, from collected records of 2132 carefully-made observations, gives a figure of

0.18 per cent. as representing the carrier-rate of virulent diphtheria bacilli in normal non-contacts, while the same observer found a carrier-rate of 10.4 per cent. among a sample of normal contacts. Stillman records a carrier-rate of 0.33 per cent. for Type 1 Pneumococci among 297 normal non-contacts, but a rate of 14.9 per cent. among 107 healthy contacts with cases of lobar pneumonia due to infection with a coccus of this type, and a multitude of similar examples could be quoted.

If a comparison be made between healthy contacts, healthy non-contacts resident in an infected area, and healthy non-contacts from an area free from the disease in question, the carrier-rates obtained may be found to form a descending scale. Flack reports a meningococcal carrier-rate of 8.53 per cent. among 1629 healthy contacts, of 5.53 per cent. among 651 healthy non-contacts from epidemic areas, and of 2.18 per cent. among 275 healthy non-contacts from unaffected localities. It is a point of some interest that, during a considerable epidemic, the carrier-rate among healthy non-contacts may equal that among healthy contacts as demonstrated by Glover in the case of the Meningococcus.

If, instead of examining perfectly healthy contacts, we confine ourselves to individuals resident in an epidemic area, and suffering from some mild atypical infection of doubtful nature, which shows no clinical identity with the epidemic disease, we find a sharp rise in the percentage of persons from whom we can isolate the specific organism. Thus we may compare the 70 per cent. carrier-rate for *B. diphtheriae* obtained by Köber when examining 139 contacts suffering from mild sore-throats with the 10.4 per cent. rate quoted above for healthy contacts. Similarly, Billet, Le Bihan, and others, while investigating an outbreak of typhoid fever in an infantry regiment, examined the faeces from 64 atypical febrile cases which could not be diagnosed as typhoid on clinical grounds, and isolated the *B. typhosus* in 13 instances, a carrier-rate of 20.3 per cent., which is vastly greater than that ever found in healthy contacts.

#### Rise and Fall of Carrier Rates in Relation to Epidemics.

In the case of cerebro-spinal fever certain additional facts have been established which are of the greatest significance. It has been shown by many observers that the rise in the meningococcal carrier-rate quite definitely precedes the outbreak of an epidemic. So uniform is this phenomenon that it has been possible to set up a tentative limit of 20 per cent. as a danger-line, and to regard a rise in the carrier-rate beyond this figure as a warning of the imminence of an epidemic. Moreover, it has been established in the case of this disease that a decline in the carrier-rate precedes the decline of the epidemic in some cases, and in others occurs more rapidly; so that it is usual for the percentage of healthy carriers to sink to a relatively low level while cases of the disease are still occurring. (Bruns and Hohn, 1907; Hutchens, 1916; Johnston, 1916; Glover, 1918, &c.) The association of a high carrier-rate with overcrowding has been noted by many observers, and Glover has given a striking demonstration of the way in which the rate may be caused to fall by simply spacing out the beds in a sleeping apartment.

#### The Virus of Scarlet Fever.

If we turn from those diseases, in which knowledge of the causative organism allows the problem to be studied from the bacteriological point of view, to other diseases in which such knowledge is still lacking we find that clinical and epidemiological studies have yielded results pointing in no uncertain way to conclusions similar to those arrived at by research along bacteriological lines.

Thus Butler, in a careful study on "The Intermittent Infectiousness of Scarlet Fever," finds ample clinical and statistical evidence to support the view that persons recovered from scarlet fever may convey the infection to others after intervals of long duration, while those who have never suffered from a typical attack may convey the disease to persons with whom they come in contact. He points out further that a statistical inquiry into the frequency with which sore-throats in other members of a household precede a fully developed attack of scarlet fever in one of them, leaves little doubt that the typical case may be the result of infection from the atypical one.

He concludes that there is little need to assume an extra-corporeal habitat for the virus of this disease, if we exclude

milk, acting as a direct cultural material, and considers that the facts point rather to the continual diffusion among the population of the scarlatinal virus, which from time to time is communicated from person to person in such toxic quantity and degree as to give rise to the typical sporadic or epidemic disease.

#### *Epidemic Diseases of Plants.*

It would be of the greatest interest to look for analogies in the epidemic diseases of plants. The relative simplicity of the conditions would seem to afford hope that the essential processes might be traced more surely than in human and animal pathology, and that we might thus gain further insight into those general principles which must surely underlie the phenomenon of epidemic parasitic disease of all kinds.

Professor Blackman, whose opinion I have asked on this point, and who has most kindly given me the benefit of his special knowledge, has pointed out to me the difficulties that lie in the way of arguing from plant to animal disease, or vice versa. The structure of the plant-bodies does not seem to afford the opportunity for the continued existence of a parasitic flora apart from disease, if we exclude cases of true symbiosis. There are no regions comparable to the respiratory and alimentary tracts, within the body yet outside the tissues, in which such a flora might readily persist. Moreover, the annual death of many of the host species, with the intervention of a relatively long period before the appearance of a new generation, introduces a factor which is altogether absent in the diseases affecting man and animals.

Another factor which makes difficult comparison between plant and animal pathology is the relative complexity of the tissue changes, and especially of the immunity reactions in the latter. The existence of a specific parasite in a plant itself constitutes disease; in man and animals it is only one essential factor.

It seems that we must be content to await further advances in our knowledge of parasitism in general before attempting to co-ordinate the facts throughout the whole field, but it is impossible to doubt that closer co-operation between investigators in all branches of biological science would be of mutual benefit, and would throw light on many of our most difficult problems.

#### THE CONCEPTION REACHED.

If we now glance back and see to what point our inquiry has so far led us, we are left with some such conception as the following:—

The first difficulty with which we were faced in forming any theory of the spread of bacterial infection, which should conform to the known facts of epidemiology, was to find some explanation of the perpetuation of the virus during inter-epidemic periods. The bacteriological data which have been accumulated, especially during the last 20 years, have shown that the causative organisms of specific diseases are to be found in apparently normal persons who give no history of having been in contact with the disease in question, as well as in healthy contacts with actual cases of the disease. Moreover, the organisms in question have been shown, in certain cases, to persist for long periods of time in or upon the tissues of their hosts, and we must always remember that the difficulty of bacteriological technique is likely to lead to a serious under-estimate.

Clinical and epidemiological investigations have yielded confirmatory evidence, and we are thus left with a conception of the virus of a given disease being distributed fairly widely throughout the world as an apparently harmless parasite on the human host, but taking on during epidemic periods a new and sinister rôle, only to relapse again into comparative quiescence as the epidemic subsides.

We have seen that while the organisms we have considered can live as harmless parasites on normal and healthy persons, yet they become much more plentiful when we examine healthy contacts, and more plentiful still if we are dealing with persons in an epidemic area who are suffering from atypical and apparently unimportant illnesses. Thus we find that a clinically typical case of a given disease tends to be surrounded by certain atypical cases, from whom the causative organisms may be recovered by suitable methods, and by a much wider circle of healthy individuals, many of whom are acting as carriers of the parasite in question.

#### LECTURE II.

It is important to keep clearly before us that the facts as to the distribution of the bacterial parasite during the epidemic period may be interpreted in two ways. It is perhaps natural to focus our attention on the case of disease, and regard it as the centre from which spread the atypical cases and the healthy carriers. There is, on the other hand, the alternative hypothesis that the distribution of the parasite is the expression of a biological process which has preceded the outbreak of disease, and that the typical cases are merely the final results of this process. We should not, of course, minimise the importance of case-to-case infection, nor cease to believe that large numbers of contact carriers derive the parasites they harbour from the sick individual.

#### THE EPIDEMIC CURVE.

If we now turn to the consideration of those epidemiological facts which must be regarded as fundamental in any attempt to form a bacteriological, or, as I should prefer to regard it, a biological conception of the processes involved in the rise and fall of a wave of disease, we find certain phenomena which from their very constancy must be regarded as of primary importance as clues to the solution of the problem.

The most striking feature is undoubtedly the symmetry of the epidemic curve. This phenomenon has been emphasised by countless epidemiologists. The problem has been clearly enunciated by Brownlee, who shows that certain deductions may be drawn with regard to the possible factors involved in the rise and decline of the wave.

We must, then, be prepared to show that those causes which bring about the rise of the wave of disease will, by their continued operation, directly or indirectly give rise to a subsequent decline in a way that is compatible with the symmetry actually observed. It seems certain that the processes leading to the fall of the wave must be the essential consequence of those causes which determine its rise. The constancy of the whole process could hardly be otherwise explained.

There are other features characterising considerable epidemics which must be taken into account, and which yield significant clues. Among these we may particularly note the occurrence during the earlier stages of an epidemic of atypical cases of disease and the reappearance, to a less extent, of these atypical cases during the latter part of its decline.

The periodicity of epidemics and the explanation of the long epidemic-free interval in certain cases form another aspect of the problem which will be referred to later.

#### *Origin and Rise of Epidemic Wave.*

Considering, then, the rise and fall of the epidemic wave, it is necessary first to find some explanation of its origin and rise. There are at least three possible explanations—an increase in the power of the parasite to produce disease, a decrease in the resistance of the host, and some alteration in the surrounding circumstances which favours the transference of parasites from case to case without any alteration in the pathogenicity of the one or in the resistance of the other. The third of these hypotheses may, I think, be disregarded. That alterations in environment may be the determining cause in initiating an outbreak of bacterial disease is probable enough; but they will almost certainly act through the variations which they bring about in the other two factors. The whole of bacteriological knowledge is clearly against the occurrence of a considerable epidemic in which the pathogenicity of the parasite and the resistance of the host remain constant.

Again, while we may well believe a lowered resistance of a certain number of the host-species to be an important factor in the initiation of the process, yet we cannot believe that it is the whole story. The widespread ravages of many epidemics would seem altogether to preclude such an explanation. We seem forced therefore to the conclusion that an increase in the pathogenicity of the specific parasite is an essential factor in the rise of epidemics, excluding from this category small sporadic outbreaks which may be due to the introduction of a fully virulent parasite by a healthy carrier or in some other way.

#### *Decline of Epidemic Wave.*

When we consider the decline of the epidemic we are faced with three similar possible factors—an alteration in

the parasite, now in the direction of lessened pathogenicity; in the host-species, in the direction of heightened resistance; or in the environmental conditions, resulting in lessened opportunities for the transference of the parasite. There is, indeed, in the case of any considerable epidemic, a fourth possibility: the elimination of all susceptible individuals by an attack of the disease. This explanation has been unanimously rejected by epidemiologists on various grounds. Brownlee, in the paper referred to above, shows that it is entirely incompatible with the observed symmetry of the epidemic curve, and that a progressive variation in the biological activities of the parasite seems to offer the most satisfactory explanation of the facts observed. But, while there seems little room for doubt that increased pathogenicity of the parasite must play an essential part in the rise of the wave of disease, it is much more difficult to decide on the relative importance of variations in the powers of parasite and host in bringing about its decline.

#### DEFINITION OF TERMS.

It is important at the outset to define our terms. "Resistance" or "immunity" expresses the sum of the defensive powers possessed by the host. When, however, we turn to the parasite, we find several terms used to denote its powers of attack, and the limits of their implications are not always clearly defined.

"Pathogenicity" denotes simply the power of producing disease, without reference to the manner in which it is brought about. It is a property of those organisms which never cause extensive tissue invasion, but which produce their effects by means of powerful exotoxins, just as much as of those organisms which give rise to a generalised infection. In referring to an organism as pathogenic for man we imply that it produces disease under natural conditions; that is, it is naturally infective, though the degree of infectivity need bear no relation to the degree of pathogenicity. When we state that an organism is pathogenic for laboratory animals there is no necessary implication that it can produce disease under natural conditions.

"Virulence" has come to mean the power of a parasite to multiply within the tissues of the host. An organism which is highly pathogenic need not necessarily be virulent. Conversely, it is possible, though rare, for a micro-parasite to be virulent but non-pathogenic. The rat trypanosome seems to afford an example, but there is no strict parallel among bacterial parasites. Virulence is indeed an elusive term. It is actually employed to express the power of bringing about a generalised infection of the host. It pays no heed to any possible variation in the power or rate of multiplication in different tissues, nor to the capacity for bringing about that initial invasion of the tissues on which subsequent events depend. Still less is virulence synonymous with infectivity; and this is a point which seems to be too little regarded in many epidemiological and bacteriological studies.

As commonly employed, the term "infectivity" denotes an attribute not of the parasite but of the diseased person, an attribute, moreover, which depends on the patient's environment quite as much as on himself. The infectivity of the typhoid patient or carrier is in inverse ratio to his personal cleanliness and to the perfection of the sanitary arrangements under which he lives. It is in direct ratio to his opportunities for contaminating food or drink. The malarial patient is infective in the presence of the anopheles mosquito, how infective recent military experience has demonstrated. In a district free from appropriate insect hosts the same patient is no danger to the community.

If we employ the term "infectivity" in speaking of a bacterial parasite, we should mean that, under the conditions existing in nature, it is in a favourable position to obtain transference to a new host, and that it is possessed of those biological attributes which will enable it, when so transferred to give rise to that sequence of events which constitutes an attack of disease.

It is incorrect, therefore, to state that an increase in the virulence of a bacterial parasite will conduce to epidemic spread of the disease to which it gives rise. It will only do so if there is an adequate degree of infectivity. In an epidemic of any disease in which virulence of the parasite is an essential factor we need an increase in both attributes to fulfil the conditions required.

#### SAPROPHYTIC SPREAD OF ORGANISMS.

In attempting to trace those processes which lead to the acquirement by the parasite of the attributes which enable it to give rise to a wave of disease, it is necessary at the start to form some conception of the manner in which it spreads from those relatively scattered centres in which we believe such organisms to exist in inter-epidemic periods.

It is of interest in this connexion to turn again to the case of cerebro-spinal fever. The evidence which has been collected with regard to this disease has already been referred to, but two further facts may be emphasised—the relatively small number of the cases of disease in any epidemic in comparison with the very large number of persons who are carrying the meningococcus, and the frequent absence of any ascertainable connexion between successive cases.

Consideration of all the available evidence has led to a conception of the spread of this disease which has met with very general acceptance, and which is clearly outlined by the authors of the recent report issued by the Medical Research Committee. It is suggested that the real epidemic consists of a widespread dissemination of the Meningococcus, as a saprophyte, in the throats of the population at large. The organism is regarded as being only a potential tissue-parasite, and as having only a low degree of virulence; so that in normal times its spread is associated only with cases of disease among the most susceptible elements of the community, that is, among infants. At times, however, the organism seems to acquire an increased virulence, and its spread is associated with a larger number of cases and with the attack of young adults who are usually immune.

Is it possible that such a saprophytic spread forms the initial stage of epidemics in general? Assuming that it does so, it is necessary to inquire whether there are valid reasons for expecting such a process to culminate in the elaboration of more infective and more virulent varieties of the parasite concerned. Certain recent observations would seem to afford ground for an affirmative answer.

#### RATE OF MULTIPLICATION OF BACTERIA AND VIRULENCE.

The rate of multiplication of bacteria in a fluid culture medium has been investigated by many observers, and more recent observations by Penfold, Ledingham and Penfold, and Chesney have yielded information of a very precise nature on this point. It has been shown that there is a "lag" phase, in which multiplication of the bacteria increases in rapidity, at first slowly and then more quickly, until a uniform rate of maximum or logarithmic growth is attained. After a time the rate of multiplication decreases, eventually giving place to a phase in which the death of organisms exceeds the rate of generation.

The relation of virulence to the phase of growth of the inoculated culture has recently been studied by Wadsworth and Kirkbride in the case of the Pneumococcus. Their results show clearly that an organism which exhibits only a low degree of virulence when injected in the form of a 24-hour culture in liquid medium may be highly virulent after being allowed to grow for 6-8 hours only in the same medium. The authors quote results which they believe to indicate a definite increase in virulence of a strain of pneumococcus by repeated subculture at 8-hour intervals, but a close study of the data given leaves a doubt whether the whole matter is not explained by the coincidence in any culture of the phases of maximum virulence and maximum rate of growth. This one point is, in any case, clearly established, and we may assume that any organism will exhibit its highest virulence under circumstances in which it is multiplying with maximum rapidity, and that a bacterium which under normal conditions is practically non-virulent may in such circumstances show a virulence of quite definite degree.

#### INCREASE IN VIRULENCE BY NATURAL SELECTION.

Now it will be clear that, in the saprophytic spread of a bacterial parasite, the conditions will tend to encourage the transference of those organisms which possess the greatest power of rapid growth, for such organisms will come to form a considerable proportion of the local bacterial flora of the host, and hence will obtain increased opportunities for transference to other individuals of the host species. In this way natural selection will operate in the direction of the dissemination of the variety of the parasite possessing a maximum power of growth under the prevailing conditions.

It would seem probable, then, that a saprophytic spread of a bacterial parasite would lead naturally to the selective propagation of those forms which would be especially likely, when introduced into the tissues, to multiply within them. It is probable that the bacteria living on a mucous surface are continually being carried into the tissues in small numbers, either by the action of phagocytic cells or in some other way. The combination of the power of rapid multiplication on the surface of the mucous membrane, with the ability to multiply in the tissues when access is gained to them, will render successful invasion extremely probable.

If, then, the parasite forsakes its saprophytic rôle and produces a localised infection of the tissues, it may be regarded as a "passage" strain. Should this strain be transferred to another individual, and so on from host to host, the analogy of experimental passage would suggest that an increase in virulence would result. Natural passage, resulting in such heightened virulence, has been frequently suggested as a possible explanation of the evolution of highly pathogenic strains of bacteria during epidemic outbreaks of disease. It is important, however, to realise that the analogy of experimental passage breaks down at a vital point.

When we wish to exalt the virulence of an organism for a given species, we proceed by transference from animal to animal, always introducing the bacteria into the tissues by mechanical means. Thus we proceed by the selection of strains which are better and better adapted for multiplication in the tissues, that is, more and more virulent in the strict sense of the term; but with the ability of the parasite to infect a new host under natural conditions we are not concerned. This attribute is, as we have seen above, of decisive importance for the production of epidemic disease.

#### *Tissue Invasion.*

If we are to accept a series of passages as the natural mode of acquirement of increased virulence, we must believe that the chances of transference, and hence of selective propagation, are increased by tissue invasion. In some cases we find ample reason for believing that such a result will follow. Whenever successful invasion results in the formation of lesions of mucous surfaces the discharges from which naturally pass to the surface of the body and are frequently or continuously emitted into the surrounding medium, it is clear that increased opportunities for passage will occur. In the case of diseases transmitted by biting insects it is still more obvious that successful and generalised invasion of the tissues will be a decisive advantage in gaining transference to a new host. Here, indeed, we are dealing with conditions which approximate closely to those obtaining in experimental passage.

It is in many of those infectious diseases in which we have good grounds for believing that transference from host to host occurs via the naso-pharynx that we are faced with the most obvious difficulty. In some cases there are, indeed, local lesions which will readily explain the infection of a fresh host, but in some others the best clinical observation reports the striking absence of local changes. Thus in the case of influenza there seems no doubt of the frequent absence of naso-pharyngeal catarrh, at least, during the height of an epidemic, while careful inquiry has signally failed to bring to light any relation between such catarrhal changes and cerebro-spinal fever.

Though these are real difficulties, they do not seem to be insuperable. The absence of localised catarrhal changes during the height of an influenzal epidemic is not paralleled in those influenza-like outbreaks which occur during inter-epidemic periods, and which, as epidemiologists have shown, tend to be especially numerous in the period preceding an epidemic wave. It would seem possible that it is during these premonitory outbreaks that the preliminary increase in virulence occurs.

#### RESULTS OF POSTULATED GRADUAL EVOLUTION OF VIRULENCE.

In this way we may perhaps explain the gradual evolution of those virulent and infective organisms which, spreading among a population, cause epidemics of disease. If this explanation be the true one, certain results must follow.

During the preliminary stages the contest between parasite and host will result in minor degrees of tissue invasion, and it is difficult to believe that such a process will not result in

the partial immunisation of the host. Again, since transference from host to host will under natural conditions be entirely promiscuous, it will often occur that a given parasite will be transplanted on a host who is already harbouring the same species, though possibly a race of a different degree of virulence. In such a case the newcomer will succeed or fail in establishing itself according as it is better or worse adapted for life under the conditions locally existing. Since it would appear to be a universal rule that competition is most severe between nearly allied species and between varieties of the same species, it is unlikely that the conditions can be so favourable for the rapid multiplication of the parasite as those existing when transference occurs to a host in whom this species is absent.

Clearly, then, the optimum conditions for successful and continued passage will be the close aggregation of a previously non-infected population, and such movement among them as will result in the entrance to the infected locality of large numbers of non-infected persons from outside areas, and the movement to hitherto unaffected districts of persons harbouring the specific parasite. In other words, unusual density of population and an unusual degree of migration will afford ideal conditions for such a process. That these conditions are those which favour the occurrence of epidemics of disease is universally admitted.

The point, then, which it seems necessary to determine is whether a series of natural passages will indeed lead to the evolution of strains of the parasite especially well-equipped for producing disease on the epidemic scale, and whether there is any reason to believe that continued variation along the same lines will result in such modifications as will render it less likely to infect new hosts.

(To be continued.)

## ON THE PROGNOSIS OF NERVE INJURIES.

By ROBERT KENNEDY, M.A., M.D., D.Sc. GLASC.,

ST. MUNGO PROFESSOR OF SURGERY IN THE UNIVERSITY OF GLASGOW;  
SURGEON TO THE GLASGOW ROYAL INFIRMARY.

### I. *Introductory.*

In order to estimate the prognosis of nerve injuries from all points of view it is necessary to have had not only a considerable number of cases, but to have had these under observation for several years. Thus it is not possible to estimate this properly from cases under observation only since the beginning of the war; for recovery of function after nerve injuries and after operations for repair is remote from the date of injury or operation. For this two things peculiar to nerve injuries are responsible. The first is the occurrence of nerve degeneration after all but the most trivial injuries and the necessity of nerve regeneration taking place before conductivity is regained. The second is the degeneration in the muscles supplied by the damaged nerve. This takes place with great rapidity, and is such that the muscle cannot become functional again until it has regenerated, and this restoration cannot begin until the nerve has already regained its conductivity.

Thus, in all cases recovery of the muscle after a nerve injury requires much time. No other kind of case is so difficult to keep under observation until the final result is attained. This is more so with cases in military hospitals, as such patients have their homes widely separated. After discharge from the army these cases can be traced, but the great majority are living at a distance and the reports received of their progress are very often prepared by those unaccustomed to report on such cases, and therefore usually unsatisfactory.

### II. *Factors Influencing Recovery.*

More than in other cases nerve injuries are influenced by many factors which have a profound effect on the prognosis, causing at times complete or partial failure, and in other cases delay of the recovery of function. These factors may be classified under the following heads.

#### A. *Factors Occurring at the Time of the Injury.*

1. *Sepsis or asepsis.*—Without doubt one of the causes most unfavourable to nerve regeneration is sepsis in the wound. At one time this was thought a complete bar to recovery, but this is not always the case, as certain cases in which very marked sepsis has been present have given good

recoveries. There appears, however, to be no doubt that it is always an unfavourable factor, and that it is apt to lead to changes in the nerve trunk and its surroundings, resulting in the formation of cicatricial tissue and permanent damage of the nerve trunk. Most of the injuries of the nerves met with during the war have been associated with sepsis and many with large septic lacerated wounds. Even when the wound has been a mere puncture a bit of cloth has often been carried in, causing destructive sepsis. This contrasts with the nerve injuries met with among civilians before the war in which the lesion was, as a rule, caused by a knife or sharp and comparatively clean chisel, or by a hit of glass or the like, making practically incised wounds, which in most cases healed up quickly. Consequently, earlier recovery was usually seen in these cases.

Although sepsis is so unfavourable in prognosis, it does not follow that its absence means an assured recovery of function. Take, for example, cases in which there is no open wound and in which the nerve has been cut by the sharp fragments of a fractured bone, or where the nerve has been ruptured by being subjected to tension. In the large majority of these no spontaneous recovery ever takes place, or at best a very trivial one. Although no sepsis has occurred in these cases other unfavourable factors have caused failure of recovery.

2. *The nature of the damage to the nerve trunk.*—This also has a very important effect on prognosis. The damage may vary between the extremes of slight compression of the nerve trunk caused by a cicatricial band to extensive loss of substance of the nerve trunk. Naturally the former would be regarded more favourably, but between the two extremes are many types of injury varying in prognosis. In general, a compression is regarded as more favourable than a severance. Yet many cases of the latter give results apparently as good as, and in some cases better than, the former, and, generally speaking, the results of the two types are practically the same. Taking the simple fact of the nerve injury, no case of severance should give a better result than one of compression, but many other factors influence simultaneously the result. Should the ends of the severed trunk not lie in close approximation, then the probability of spontaneous reunion is not good. Further, if there is separation to any great extent the gap will not be bridged successfully, and failure of reunion will certainly result.

3. *The surroundings of the damaged nerve trunk.*—The condition of the surroundings is very important. As in shell wounds, much destruction implies cicatrization in the vicinity of the nerve, so that even although the nerve itself had been in a condition for recovery, yet the development of a mass of densely contracted cicatricial tissue makes any recovery impossible. Sometimes it apparently does not require very much contraction to destroy the function of the nerve, the most notable examples being in the case of the ulnar sulcus and in the aqueduct of Fallopius. In both cases complete and permanent loss of the conductivity of the respective nerves is found from comparatively small amounts of cicatricial tissue.

4. *Amount of trauma.*—A clean cut severing a trunk as a rule gives a better prognosis than when the severance is made as part of a lacerated wound, and when the laceration is extreme the unfavourable effect is extreme. The mode of action of trauma is apart altogether from any loss of substance of the nerve trunk, and still is unfavourable even although the nerve is not actually divided. The harmful effect is due to the reaction in the tissues, in the nerve itself, and in its surroundings, of such a nature that there is more apt to be a development of cicatricial tissue and therefore ultimately compression.

5. *The nerves injured and situation of the injury.*—Certain nerves are more difficult to deal with than others, and in injuries of these prognosis is less favourable. For example, injuries of the facial nerve are difficult to repair. In the first place, injury in the aqueduct is practically impossible to deal with because of the surroundings of bone. There is no difficulty in exposing it here, but the results are unfavourable for the reason stated. Also, if injured in its course in the parotid its repair is very unfavourable because of the salivary gland; while beyond the parotid the tenuity of its branches is against the chances of a favourable reunion. In general, up to a certain size the larger the nerve trunk the more likely is a good result either from the point of view of spontaneous reunion or of reunion by operation. In the

former case the ends are not so likely to be separated by an interval so great in proportion to the thickness of the trunk than is the case with nerves of greater tenuity. In the latter case the larger trunks are more easily found and less damage is done to the tissues in the process of finding them.

Then, again, there is the fact that the same nerve will have a better prognosis in certain situations than in others. The best illustration of this is the ulnar nerve, which has its worst prognosis when wounded in its course in the ulnar sulcus unless operative means are adopted to overcome this.

Also, the level at which a nerve is severed has its effects on the result. The most unfavourable event is when the nerves are pulled from the cord, so that the injury is presumably an intrathecal one. The most frequently occurring instance of this is in the brachial plexus, which is sometimes completely torn out by a pull on the abducted arm, the effect being to pull out the nerves from the cord and totally paralyse the arm. The arm then may be amputated at the shoulder, as it would only be a trouble to the patient, and even then sometimes intolerable neuralgia having its origin at the intrathecal lesion continues.

#### B. *Lapse of Time between Injury and Operation.*

1. *The progressive atrophy of muscle.*—Wasting of the muscle supplied by the injured nerve is the most serious effect of a nerve lesion, and affects the prognosis very materially. This wasting commences immediately the nerve loses its conductivity. It is unnecessary to go into the exact changes in the muscle, but their effect is to cause the latter to alter almost immediately in its electrical reactions, and when, after a short time it is exposed, it is paler than normal and wasted. For a very long time certainly it retains its responses to galvanic stimuli, although it goes on wasting until its bulk is very greatly reduced.

It is this effect on the muscles which must be taken into account very carefully in giving a prognosis. In the first place recovery of motion will not occur until the muscle is again largely built up and restored to a condition in which its electrical reactions are normal. In the second place the time required to effect this will not be the same in each case, but will vary very widely according to the extent of wasting which has to be made up before recovery exhibits itself to the extent of voluntary movements being possible. Recovery of faradic irritability in the affected muscles is, as a rule, the immediate precursor of recovery of voluntary contractions in the muscle.

Now it is only by a careful study of many cases over long periods that accurate data could be got to formulate a law as to this recovery. In a general way it is recognised that if operation for the reunion of a severed nerve is long postponed any recovery possible will be much longer delayed than if the operation had not been so delayed. The cause of this, as just stated, lies principally in the state into which the muscles have fallen.

2. *Primary and secondary suture.*—In this connexion the question will arise to what extent primary suture has the advantage over secondary suture. The answer is that, other things being equal, it will secure the recovery of the nerve at the earliest possible time so as to stop the degeneration of the muscle as early as possible, and therefore be most advantageous. But other things are not always equal, for in the nerve sections seen in the war the conditions for primary suture were not favourable as a rule, the wound being usually lacerated and infected. In consequence, even although the nerve has been sutured primarily, the result will probably be failure, secondary suture being required. In any case no longer than four months, everything being favourable for further operation, ought to be allowed to elapse after the primary suture without resorting to secondary operation, unless some definite indication has developed to prove that the nerve is renniting.

Then with regard to the question of when to operate when primary suture has not been done, in order to secure the best result, there may be contingent circumstances influencing the decision, such as an open wound. In that case the wound must first be induced to heal, as the prognosis of an operation in such circumstances would not be good. Should the parts be healed sufficiently long and only the question of time to be considered, then between two and three months after the nerve section appears to give a prognosis of the earliest possible recovery. Under such circumstances the best result is a recovery of voluntary movements in about three or four months from the date of operation.

When further delay has taken place before operation then the waiting time after the operation increases at a greater rate. Thus the examination of a number of cases showed that cases operated upon within three months gave a commencing recovery in three and a half to four months, but if five or six months elapsed before operation then seven or eight months elapsed before any improvement in the muscles occurred. These dates refer entirely to the recovery in the muscles. The date of recovery of sensation is not dependent on these intervals of time.

3. *Operation after long intervals.*—When many months have been allowed to elapse before operation then the date of recovery of the muscles is so remote and so gradual that it is very difficult to say exactly when it has commenced to exhibit itself. These cases often pass out of observation and are seen only after a long time, when it is found that recovery has taken place.

FIG. 1.—Condition in Case 1 before operation and 18 months after division of ulnar nerve above wrist. (Phil. Trans., B, 1897.)

CASE 1.—The patient was a woman aged 29. The ulnar nerve was divided above the wrist 18 months previously. At the operation the nerve was found completely divided and the ends separated. Before the operation the muscles in the hand supplied by the ulnar had lost all their voluntary power; their faradic irritability was lost and their responses to the galvanic current were minimal. The muscles were wasted and the skin glossy; the appearance of the hypothenar eminence is shown in Fig. 1.

The operation was performed in January, 1897, 18 months after the section of the nerve. Sensation in the insensitive area returned in five days, indicating the recovery of the

FIG. 2.—Condition in Case 1 five years after operation. (Chippault's, *Chirurgie Nerveuse*, vol. ii., Paris, 1903.)

conductivity of the nerve, but no appearance of recovery of the muscles was exhibited and the patient passed out of view and the case was published at this stage. She was seen again five years and four months after the operation, and it was found that a perfect recovery of the muscles and of the movements had occurred in the interval. Fig. 2 shows the reproduction of the hypothenar eminence which had taken place. The slight appearance of hyperextension in the little and ring fingers was the consequence of the long-continued ulnar attitude, but did not prevent the normal use of these fingers.

Another case may be quoted in illustration of this matter. It was a case of rupture of the fifth and sixth cervical nerves in the brachial plexus.<sup>1</sup>

CASE 2.—The age of the patient at the operation was 14 years, and the accident occurred at birth. The typical paralysis of this condition was present with atrophy of the affected muscles. At the operation the fifth and sixth trunks were found to have been completely divided and united by a scar. On stimulation only a few of the fibres of the deltoid and biceps contracted without any movement resulting. The cicatrix was excised and the proximal two trunks sutured to the three distal branches—namely, supra-scapular nerve, branch to the posterior and branch to the outer cord of the plexus. At five months no improvement had occurred in the movements, although the electrical reaction seemed improved. About two years after the operation, however, the movements had greatly improved.<sup>2</sup> The forearm could then be flexed voluntarily through a range of 60°, and voluntary abduction of the arm was possible through a range of 45°. While these movements were being made the biceps and deltoid could be felt to contract. Also the atrophy of the biceps and deltoid had greatly disappeared. This was the state of matters on the last occasion on which the patient was seen. He wrote subsequently stating that his arm was "all right now," meaning, probably, that further improvement had taken place. No further occasion to examine him occurred, and it has since not been possible to trace him.

It is thus seen that even after long periods there is a possibility still of obtaining good results. It also seems to be the case that although delay in operating means an increasingly longer period to wait for the recovery, after longer delay before operation, the recovery takes place in a more uniform interval of time. Thus for increasing intervals before operation the waiting time after operation increases up to a point and then ceases to increase with further increase of the interval before operation.

#### C. Factors Occurring at the Operation.

1. *Asepsis or sepsis.*—Asepsis is one of the most important conditions in operations for the repair of damaged nerves. A standard of technique which may give passable results in certain other branches of operative surgery will give poor results in nerve surgery. The importance of this as regards the prognosis is not always kept in view. The special reason for this high standard of aseptic technique is that we are dealing with the regeneration of one of the highest types of tissue cells which, as far as their regenerative capacity is concerned, are inferior to connective-tissue cells. The latter, if present in abnormal quantity, are likely to prevent the development of nerve tissue simply because they regenerate more easily than nerve tissue. The consequence is that compression will ultimately develop from the new-formed connective tissue which is fatal to the functional development of any new nerve fibres which have been formed.

It is not only a question of healing by first intention. Certain wounds may heal by first intention, although a more considerable reaction has occurred in them than in the case of other wounds in which the state of sterility has been more successfully guarded. Thus it is that the surgeon whose technique has nearest approach to perfection will find his results better than where the technique is not quite so good, although in both cases all the wounds may have healed "by first intention." It is not meant by this to maintain that no result is possible should a wound even suppurate, for a good result may take place although sepsis has occurred, but in general the results will be better the less the reaction induced in the wound, and this reaction can be reduced to a minimum by technique.

2. *Amount of trauma caused by operation.*—Very important is the amount of force necessary at the operation before the scar is removed from the nerve and its surroundings so as to leave the nerve free or before the ends of the divided nerve are freed from scar and united by suture. Usually the operation, carried through with the greatest gentleness, will give a quicker result than one where force has been necessary. The rule is always to avoid force or coarseness of manipulation if the object can be attained without. This rule applies to any department of operative surgery, but failure to observe it is particularly destructive of good results in nerve surgery. When the nerve ends are embedded in dense scar it is not always possible to get the nerve trunks clear without considerable force. Also, in the case of

<sup>1</sup> Brit. Med. Jour., 1903, Feb. 7th.  
A 2

<sup>2</sup> Ibid., 1904, Oct. 22nd.

a lesion of the ulnar nerve in the arm when the ends cannot be united, without transferring the nerve out of the sulcus to the front of the epicondyle, then more trauma is inflicted. In such cases the prognosis is not so good as where minimal force and manipulation are used.

3. *Coaptation of the nerve ends.*—Another important point is the possibility of getting the ends to meet. If they do not meet, or only do so with tension on the nerve, then the outlook is not a good one. Sometimes if the ends are separated only by a short interval conductivity is restored, but sometimes it is not. Nevertheless, the failure to get the ends quite to meet is much less serious than infection of the wound would be. When the ends do not meet pulling on the nerve trunk often succeeds in getting them together, but the fibres of the nerve may be ruptured, and in that case will require to regenerate causing a further postponement of the early signs of reunion. Excising a segment of a bone so as to shorten the limb and bring the nerve ends into contact requires so much manipulation that the prognosis is unfavourable.

4. *The nature of the suture.*—The suture used has some importance. When sutures which cause irritation have been used, such a formation of connective tissue may be caused at the seat of suture as to strangle any young nerve fibres and prevent restoration of conductivity. The suture must be carefully chosen in view of its capacity either to be encapsuled by the tissue or to be absorbed and to cause the least irritation in either process. Also those cases will have the best prognosis in which the smallest amount of foreign material has been left at the seat of section either to be encapsuled or absorbed. This applies to Cargile membrane or any dead material employed to wrap round the seat of junction, also to thick sutures or many sutures at one junction, all of which are objectionable.

5. *The surroundings in which the nerve is left.*—Lastly, the prognosis is poor in all cases in which after the operation the sutured or liberated nerve has unavoidably been left in a bed of scar or in a bony canal or furrow. In the former case the scar will contract and prevent the conductivity of the nerve from being restored or destroy it after it has been restored. In the latter case the scar or neuroma which is formed at the damaged segment of the nerve, because of the unyielding boundaries, will prevent conductivity by compression.

#### D. Factors occurring after the Operation.

1. *Contraction of antagonist muscle or group of muscles.*—After a satisfactory operation a case may be spoiled by the want of attention to the antagonist of the paralysed muscle or group of muscles. The paralysed muscles may recover their irritability and yet be incapable of carrying on their function because they are stretched and cannot overcome the contracted muscles. This can be prevented by appropriate fixation or even by appropriate passive movements until recovery of the paralysed muscle.

These contractures appear to be more apt to occur in injuries of certain nerves, but again they are also found in certain cases and not in other cases of injury of the same nerve. The difference appears not always to lie in the amount of attention given to the limb throughout the period of recovery. Thus, although no correcting splint has been applied, excellent recoveries may result. In some cases most favourable results are obtained without the slightest attention to after-treatment.

For example, a case of musculo-spiral paralysis<sup>3</sup> after operation gave a complete recovery, although the patient did not permit any after-treatment whatever. A fracture of the humerus was caused by the patient being run over by a police van from which he had just made his escape by tearing up the floor and dropping on to the street. Two days after operation for nerve suture he left the hospital and for about ten days was practically continuously under the influence of drink. He then called at the infirmary and had the stitches removed from the wound, which had healed perfectly by first intention. No more was heard of him till five months after operation when he called again and showed a perfect result and stated that the recovery had become apparent to him 9½ weeks after the operation. In this case the operation was done as soon as the nerve was in the best condition for operation, so that a minimum time was allowed for the development of contracture.

As a rule, contracture will be more likely to affect the prognosis when recovery is longer delayed, and if it is

allowed to develop to a marked degree it will seriously hinder the recovery. Thus when contracture is well developed it often happens that although there appears to be no recovery of the paralysed group, that group is found on electrical examination to give normal reactions, but the functional recovery has been made impossible by the over-stretching due to the contracture of the antagonist group. This very often is shown in cases of foot-drop, where not only the paralysis of the extensors, but also gravity combine to keep the foot in a position of flexion and thus the formation of contracture of the flexor group is encouraged. Unless care is taken this contracture will prevent a functional recovery of the muscles. The contracture must either be prevented from forming or dealt with should it already have formed.

CASE 3.—Figs. 3 and 4 show a foot in flexion and extension, and in this case there was foot-drop due to an injury of the external popliteal nerve. It was dealt with four months

FIG. 3.

FIG. 4.

Case 3.—Recovery of extensor muscles after injury of external popliteal nerve followed by contraction of gastrocnemius dealt with by section of tendo Achillis.

after injury, at which time the extensor group still showed galvanic reactions but no faradic responses. The patient lived at a distance from the hospital and reported himself after the operation very seldom. It was found in about three months that contracture of the gastrocnemius had occurred. The tendo Achillis was then divided for the temporary relief of the contracture. The patient did not report himself again for two years, when it was found that the extensor group had recovered perfectly, and the tendo Achillis not having reunited the foot was drawn into a position of calcaneus. The tendo Achillis was then repaired. The patient then returned to his work as a miner. It is now 2½ years subsequent to the repair of the tendon, and a slight calcaneus position still remains. Had the patient been more regular in his visits to the hospital the tendo Achillis could have been repaired as soon as the extensor group had recovered, and thus the development of the calcaneus prevented. This method is advisable only when the patient cannot be attended to regularly or induced to wear a correcting apparatus pending the recovery of the muscle.

2. *Cicatricial contraction.*—In certain cases it is learned on questioning the patient that sensation was present after the receipt of the wound, and that the anaesthesia developed subsequently at no great time after the injury. Then, in all probability, the nerve will be found not divided, but compressed in cicatrix. The loss of sensation has been due to cicatricial contraction and comes on gradually. The same is sometimes observed after operation, a very early return of sensation gradually disappearing a little later and no improvement again showing itself. This is to be expected, as already noted, when the nerve at the operation is left in dense surroundings or in pre-existing cicatrix.

3. *Overwork on recovery.*—Muscles which have just recovered their function are incapable of doing much work, any attempt by the patient to make them work will result in fatigue which will hinder further recovery. The paralysis then recurs and remains until the muscle from the enforced rest again becomes functional. This may not mean that the man is overworking his muscles by a return to work. The same thing can occur by any ordinary use of the muscles. It sometimes happens that a man finds the recovering hand strong enough to grasp the handle bar of a cycle and commences to use this means of locomotion. This is frequently followed by a recurrence of the paralysis. It is well to advise patients as to the use of the hand in the early stages

<sup>3</sup> Chipault's *Chirurgie Nerveuse*, ii., 855, Case 33.

of recovery. Active movements should be strictly limited until the muscles are sufficiently strong.

III. Results.

In 1908 I published a series of all the nerves operated on by me to that date. There were 35 in all, but ten were too recent to give final results. Some of the latter were subsequently traced and found to have given satisfactory results. There remains a series of 25 observed for a sufficiently long time, and of which the main details can be seen by reference to the work in which they were published.<sup>4</sup> A certain number of these cases were found at the operation to be cases of complete severance and the remainder to be cases of compression.

For the purpose of classification the results were divided into three categories, namely: Complete Successes, i.e., where sensation and motion were restored so as to give restoration of normal function; Partial Successes, i.e., where the results left something wanting, although the recovery was sufficient to give distinct improvement; and Failures, i.e., where no useful recovery resulted.

Tabular Statement of Results in 25 Fully Observed Cases.

Nerve or nerves affected.	Complete severance.				Compression.				Total.			
	Number.	Complete success.	Partial success.	Failure.	Number.	Complete success.	Partial success.	Failure.	Number.	Complete success.	Partial success.	Failure.
Brachial plexus	1	1	...	...	2	1	1	...	3	2	1	...
Median ...	3	3	...	...	...	...	...	...	3	3	...	...
Ulnar ...	6	4	2	...	1	1	...	...	7	5	2	...
Musculo-spiral	3	2	1	...	3	3	...	...	5	1	...	...
Radial ...	1	1	...	...	...	...	...	...	1	1	...	...
Median and ulnar	1	...	1	...	1	...	1	...	...	2	...	...
Median, ulnar, and musculo-spiral	...	...	...	...	1	...	1	...	1	...	1	...
External popliteal	...	...	...	...	1	1	...	...	1	1	...	...
Facial...	...	...	...	...	1	1	...	...	1	1	...	...
Total results	15	11	4	...	10	7	3	...	25	18	7	...
Percentage ...	...	73.3	26.6	...	...	70	30	...	...	72	28	...

The accompanying table shows these results as regards the nerve or nerves affected, the nature of the lesion, viz., complete division or compression; the whole of the cases considered together and the nature of the results. It is seen that there are no failures, and that the results are not greatly different as between complete division and compression.

EYE-COLOUR AND THE ABNORMAL PALATE IN NEUROSES AND PSYCHOSES.

By H. LAING GORDON, M.D. EDIN.,  
PHYSICIAN TO THE LANCASTER CLINIC OF PSYCHOTHERAPY.

THE influence of the individual factor in the development of neuroses and psychoses is of importance in relation to their prevention. The lack of reliable data for a detection or estimation of the factor, which has also social and economic aspects, becomes evident in examining soldiers afflicted by these disorders. The conviction grows that the part played by nature, as distinct from that of nurture, in the development of such disorders cannot yet be described safely as more than a susceptibility (predisposition).

The view, however, that definite indications of nature's influence are demonstrable before disorder reveals it, is held widely. Physical stigmata are pointed out, and the importance of stigmata cannot be overrated if their significance be proved and they provide a means of estimating the degree of susceptibility. But their significance cannot be taken as proved, and no claim has been made for their mensurative use. Yet "instability," "neurotic constitution," and

"degeneration" continue to figure freely in up-to-date textbooks without explanation of their meaning, and stigmata to be described under symptomatology as indicative of these terms. It would appear that the first two of the terms are meant to be synonymous with susceptibility.

On this assumption, advantage was taken of the opportunity afforded by the examination of a long series of discharged soldiers in whom susceptibility to neuroses and psychoses had been demonstrated only by its results, to inquire into accepted and unaccepted stigmata. The accompanying notes on eye-colour and the abnormal palate represent the results of observations forming part of this inquiry.

Eye-colour.

The observations upon eye-colour were made to test a prevailing impression that the sufferers from (war) neuroses and psychoses are mostly dark-eyed, and after these considerations:—

1. Previously to 1914 at least, it was believed that nations varied in susceptibility to neuroses and psychoses. The susceptibility of the British was believed to be low, that of certain continental nations to be high.

2. The dominant eye-colour of these continental nations is dark; that of the British is believed to be light.

3. The impression that dark eye-colour predominates amongst the British (war) sufferers from neuroses and psychoses, coupled with the impressions contained in (1) and (2), suggested that the inquiry might prove interesting and possibly productive.<sup>1</sup>

A preliminary search was made for records of the relative frequency of the different eye-colours amongst our population but not with satisfactory result owing to the variation in standard of colour and in methods of record amongst the observers (Beddoes, Tocher, Ripley). Nevertheless, the inquiry was pursued in hope that reliable figures would be produced by scientific observers in our great armies. The method of observation adopted was founded on that employed by Major C. C. Hurst, F.L.S., in the Burbage inquiry into Mendelian inheritance in man,<sup>2</sup> and based upon the anatomical distribution of the eye pigment.

"In the albedo pigment is absent; in the various shades of blue eyes the pigment cells are confined to the posterior surface of the iris, whereas in grey, brown, and black eyes pigment is found also in the cells of the stroma and in those of the endothelium on the front of the iris."<sup>3</sup>

In effect the method divides eyes into two classes: first, those with pigment in the posterior layer of the iris only; secondly, those with brown pigment *also* in the anterior layer of the iris, in the stroma, or in both. Hurst named the first class *simplex*, the second *duplex*, eyes. *Simplex* eyes are therefore always some shade of pure blue or pure "grey."<sup>4</sup> *Duplex* eyes comprise all other colours—black, brown, hazel, yellow, green, impure grey, and intermediate shades. Neither confusion nor hesitation need occur if the question of colour is steadily excluded from the simple decision whether (brown) pigment is present anteriorly in the iris or not. The method—easily learnt and rapidly carried out by careful inspection laterally in a good light—is facilitated by Hurst's further subdivision of *duplex* eyes into *self*, *ring*, and *spotted*, according to the pattern of distribution of the anteriorly placed pigment.

The observations were made in three series of consecutive cases (Table I.):—

TABLE I.

	Series A.			Series B.			Series C.	Total.
	1st 100	2nd 100	3rd 100	1st 100	2nd 100	3rd 100	100 cases	700 cases
Simplex ...	33	34	27	37	33	31	35	230 ... 32.85%
Duplex ...	67	66	73	63	67	69	65	470 ... 67.15%

Totals } Simplex, Series A, 94, 31.33% ... Series B, 101, 33.66%  
          } Duplex,     ,,   206, 68.67%     ,,   199, 66.34%

<sup>1</sup> An eminent physician assures me that history supports a belief that the blue-eyed races have proved their superiority over the brown-eyed and points to a number of contemporary illustrations of the fact that great leaders are frequently blue-eyed, even among the brown-eyed nations. On the other hand, there is the epigrammatic French view (A de Candolle) "Pigmentation is an index of force."

<sup>2</sup> Eugenics Review, April, 1912.   <sup>3</sup> Gray's Anatomy, 1913, p. 942.

<sup>4</sup> That is to say "grey," in the opinion of some. It is the absence of pigment anteriorly that matters rather than the observer's conceptions of colour.

<sup>4</sup> Chipault's Chirurgie Nerveuse, ii.

In the absence of statistics as to the relative frequency of simplex and duplex eyes in our population, these figures cannot be advanced to do more than support the prevailing impression that the duplex eye is more frequent than the simplex eye amongst our (war) sufferers from neuroses and psychoses.

#### Palate.

The abnormal palate has a strong position in medical opinion as a stigma of "degeneration," which, we are told, is capable of manifesting itself in "nervous instability." Observations on the palate were therefore introduced into the inquiry at the suggestion of a colleague. An attempt was made to follow Peterson's classification of abnormal palates, but this was discarded as too complicated and confusing as soon as an ocular conception of the normal palate had been acquired. The method adopted finally took narrowness as a characteristic and abandoned height, which experience suggested to be more apparent than real, and included the shape of the arch not only as a characteristic, but also as an indication of the intensity of the abnormality, as follows:

1st Norman (N<sup>1</sup>) = wide round arch = normal palate.  
2nd (N<sup>2</sup>) = narrow " " = abnormal (1st degree).  
1st Gothic (G<sup>1</sup>) = " oval " " (2nd " ).  
2nd " (G<sup>2</sup>) = " pointed " " (3rd " ).

This division, like Peterson's, is arbitrary, but has the advantage of simplicity. No data were discovered in medical literature for an anatomical division; the normal width of the palate relatively to the dimensions of the facial skeleton does not appear to have been ascertained. Faute de mieux the classification seemed to serve for as accurate observation as is possible at present to the trained eye.

The palates were observed in two series.

TABLE II.

Series A (as above). 163 cases only.

N <sup>1</sup>	N <sup>2</sup>	G <sup>1</sup>	G <sup>2</sup>
28 ... 17.17%	47 ... 28.84%	69 ... 42.34%	19 ... 11.65%

The striking feature of the result in Table II. is the low returns for the "normal" palate and for the extreme degree of abnormality, and it was thought worth while to ascertain how simplex and duplex eyes were distributed to the varieties of palates in the series. (Table III.)

TABLE III.

Series A (163 cases only).

Eyes.	Palates.				Total (eyes).
	N <sup>1</sup>	N <sup>2</sup>	G <sup>1</sup>	G <sup>2</sup>	
Simplex	9 ... 32.14	16 ... 34.05	18 ... 26.05	4 ... 21.05	47 ... 28.83
Duplex	19 ... 67.86	31 ... 65.95	51 ... 73.95	15 ... 78.95	116 ... 71.17
Series C (100 cases).					
Simplex	10 ... 47.6	15 ... 48.7	9 ... 23.7	1 ... 10.0	35 ... 35.6
Duplex	11 ... 52.4	16 ... 51.3	28 ... 76.3	9 ... 90.0	65 ... 65.0
Above Cases Combined (263 cases).					
Simplex	38.77	39.75	25.23	17.25	31.18
Duplex	61.23	60.25	74.77	82.75	68.82

The leading feature of the result in Series A suggested a further series and Series C was undertaken only to ascertain if that feature was maintained, while the results of the combination of Series A (163 cases) with Series C (100 cases) are also tabulated.

It will be seen that while the percentages of the least abnormal (N<sup>2</sup>) show small variation from those of the normal (N<sup>1</sup>), those of the abnormal classes (N<sup>2</sup>, G<sup>1</sup>, G<sup>2</sup>) show a progressive increase of the percentage of duplex eyes as the degree of abnormality of the palate increases. The difference between the percentages of duplex eyes in N<sup>1</sup> and in G<sup>1</sup> and G<sup>2</sup> is in fact as definite as the difference in palate formation. The similarity of the percentages of N<sup>1</sup> and N<sup>2</sup> may be explained, plausibly at least, by the fact that the departure from the normal in N<sup>2</sup> consisted of narrowness without change in arch formation.

The doubt arises whether there has not been faulty classification—that many of N<sup>2</sup> should have been classed in N<sup>1</sup>. This doubt must beset such classifications until the

width of the palate relatively to the dimensions of the facial skeleton is determined. This consideration, however, does not affect the fact that the figures show a by no means negligible increase of the percentage of duplex eyes in G<sup>1</sup> and in G<sup>2</sup> (the definitely abnormal palates) over the percentage of duplex eyes in N<sup>1</sup> (the normal palates).

#### Conclusions.

Definite conclusions are prevented by the facts already noted, but the following suggestions seem justifiable:—

1. That in individuals who are susceptible to the neuroses and psychoses duplex eyes are more than twice as common as simplex eyes.

2. That in the same class of individuals the narrow and abnormally arched palate (G<sup>1</sup> and G<sup>2</sup>) is present in about 52 per cent. of cases.

3. That in the same class, again, the proportion of duplex eyes to simplex eyes is markedly increased in those cases with narrow and abnormally arched palates (G<sup>1</sup> and G<sup>2</sup>) and the increase tends to intensify along with the intensification of the palatal abnormality.

Even if the proportion of simplex to duplex eyes given does not vary from the general proportion in our population and even if the abnormal palate is indeed a British characteristic, whatever its cause, the interest of the third conclusion remains sufficiently suggestive for further investigation on a larger and more complete scale.

#### Degeneration.

A word must be added on the subject of the abnormal palate as a stigma of "degeneration." Bearing in mind the view explaining the abnormality by the baneful influence of adenoids on intranasal air pressure, their presence was looked for whenever recognised characteristics of their influence (adenoid facies) were detected in Series C.<sup>6</sup> This happened in class G<sup>2</sup> only, but in all ten cases; and adenoids were found, or a history of operation, in six of these. By way of control after each case the next case classed as G<sup>1</sup> was examined for adenoids, but without result.

It would appear that the reply of the "degeneration" theorist to the air pressure theorist has been to sweep in adenoids as a stigma.<sup>7</sup> I do not venture to decide how far my figures may support one side or the other. The publication of these notes, however, is certainly not prompted by a desire to strengthen the position of the abnormal palate in the fabric of "degeneration," or to nail up the duplex eye as a new stigma; or yet to justify the tendency to use "degeneracy" and "neurotic constitution" as synonyms.

Etiologically, "degeneration" signifies downward departure from the qualities of the race—a definition offering too welcome latitude to indolent judgment and inviting us to stigmatise many whose accomplishments prove us wrong. If "degeneration" and "neurotic constitution" are to be retained in medical terminology, then surely clear thinking demands that they should be raised to the level of scientific exactitudes.

I venture to repeat that susceptibility to neuroses and psychoses is the most our present knowledge permits us to premise. So far as the observations, of which those recorded here formed part, have gone, they create a belief that reliable data for the estimation of this susceptibility, if attainable, may be reached more readily through psychopathology than through somatic pathology.

Little that is illuminating on this subject has so far appeared to my knowledge in the flood of medical literature of the war; while Freud, Adler, and Jung similarly fail us, although some of the latter's abstract reasoning in his "Conception of the Unconscious" is suggestive. It is not sufficient to speak of symptoms and pride ourselves we have proved "neurotic tendencies" or "instability" without having any conception of their fundamental cause. The way of enlightenment may perhaps lie through further investigation of the complicated psychic processes of the child, of which, as Jung confesses, our knowledge now is meagre.

<sup>6</sup> Previously to observing Series C I had the advantage of a demonstration by Dr. Harry Campbell of his well-known views on the causation and significance of the abnormal palate. It will be recalled that he is inclined to regard it as a British characteristic, denying its connexion with degeneracy.

## A CASE OF PITUITARY TUMOUR TREATED BY OPERATION.

By H. LAWSON WHALE, M.D. CANTAB., F.R.C.S. ENG.,  
LARYNGOLOGIST TO THE HAMPSTEAD GENERAL AND TO THE  
LONDON TEMPERANCE HOSPITALS.

THE following case of pituitary tumour is, I think, worthy of record. Sellar decompression and removal of endotheliomatous tissue from the anterior lobe of the gland was followed by great improvement in the pressure symptoms.

### *Condition of Patient.*

Mrs. —, aged 29 years, consulted Dr. C. O. Hawthorne in September, 1917. The chief points in her condition were as follows. Sight failing for six months. Sleepy and easily fatigued. Weight, if anything, gaining. No digestive disturbances. Married for four years. Amenorrhoea for four years. Patient was, for her age, a heavy, lethargic woman. Spoke in a slow monotone and walked slowly. Wassermann negative. On one occasion only was sugar found in the urine. Optic discs white. Vision: R., 6/24; L., 6/60. Visual fields, roughly tested, showed deficiency in temporal halves nearly to fixation point (see chart). The patient was seen by Mr. E. D. D. Davis.

In November, 1917, patient was under observation in Hampstead General Hospital. Vision:—R., 6/18; two letters, 6/12. L., counted fingers at three feet. Temperature never above normal and morning record often 97° F. Blood showed leucopenia (2500 white cells). Occasional vomiting sometimes occurring in the morning before any food had been taken. In December, vision: R., 6/18; L., fingers at two feet. Thought her sight was better than on admission. The patient was seen by Mr. W. G. Howarth. In June, 1918, after having been to Yorkshire, thought this had resulted in a wonderful effect on general health and eyesight. Looked much more alert and had largely lost her

FIG. 2.

The pituitary fossa is enlarged both vertically and in the sagittal plane. The anterior clinoids are deformed and thickened; the posterior clinoids are atrophied, thick and rounded.

when sight (left) began to fail. Lethargy was obvious. Her sugar tolerance had been tested. She took up to 5 oz. in eight hours without any appearing in the urine. Nose and accessory sinuses normal. Skiagram, taken by Mr. H. Wigg, showed a large pituitary fossa (Fig. 2). Her husband was decisive in preferring the risks of an operation to a continuance or aggravation of her condition. A nasal douche, and urotropin 20 gr. t.d.s. were prescribed for four days as a preliminary to operation.

FIG. 1.

*Perimetric charts.*—Neither before nor subsequent to operation was there any record of vision in the temporal fields, excepting from March 22nd to March 29th, between the lines 90 and 45 in the upper part of the right side. But the improvement in the nasal fields is striking. Continuous black line — Sept. 18th, 1917. Interrupted black line - - - March 22nd, 1919. Dotted line ..... March 29th, 1919. Immediately previous to the operation the fields were not charted, because on the left side she had only perception of light.

former lethargic expression. Vision: R., 6/9; L., perception of light only. On Feb. 22nd, 1919, she had been seen as an out-patient on two or three occasions, and lately condition had been less satisfactory. Vision: R., 6/24; L., perception of light only. Headaches began six months ago and were now worse, especially in the mornings.

On March 4th I was asked to see patient. Headache was now acute and nearly constant in the vertex or the occiput. Occasionally there was a moderate degree of proptosis (left), which at other times was absent; divergent squint (left). Questioned as to previous diplopia, patient stated that this had existed two years ago, but only lasted three months,

### *Operation.*

Operation was performed on March 8th, Dr. B. W. Cohen assisting. Preliminary laryngotomy had been intended, but the available tube was unsuitable. As the patient was breathing badly under the anæsthetic an airway had to be provided without loss of time. Rather than delay until a tracheotomy tube could be boiled and inserted the available tube was inserted through the thyro-hyoid membrane; through this tube Dr. D. H. Fraser gave chloroform, the pharynx being shut off by sponges. The tube was withdrawn eight hours later. The left middle turbinate was now removed.

A modified Mouré's incision was made on the left side. The vertical limb of this took the ordinary course down along the junction of nose and cheek. The horizontal limb passed outwards in the skin only as far as just beyond the punctum lacrymale. Thence it was carried through the lower tarsal plate and along the deepest part of the conjunctival fornix for  $\frac{3}{4}$  in. The bone, now removed with saw, chisel, and bone forceps, was bounded as follows: mesially, by the pyriform opening and the inter-nasal suture; above, by a horizontal line cutting off a bare  $\frac{1}{2}$  in. of the nasal process of the frontal bone; laterally and below, by a line from the centre of the infra-orbital margin to the middle of the pyriform opening (this line just spared the infra-orbital vessel and nerve); laterally and above, by a curved line skirting the infra-orbital margin.

The naso-antral party wall was now freely cut away; the nasal duct was not seen or recognised. The ethmoidal gallery was nibbled away and the sphenoidal cell identified. Of this the whole outer wall was cut away. At this stage I had been prepared to sever the bony septum from its attachments above and to dislocate it temporarily to the right for better access to both sphenoidal cells; this manœuvre, however, proved unnecessary. The whole cavity was carefully cleared of minute fragments of bone and mucosa and swabbed, and fresh adrenalin applied for five minutes. The sellar floor was now to a large extent removed piecemeal by the use of one of the curved gouges belonging to a West's intra-nasal dacryocystotomy set. The bone was seemingly very thin. No force at all was required.

What appeared to be a collapsed cyst, which when intact would have been about the size of a small cherry, presented.

FIG. 3.

Photographed on May 5th, two months after the operation, and two weeks after the patient had returned home to the normal performance of all her household duties. The visible scar of the incision, already small, may later be entirely obliterated by excision.

nasal incision, through which a fine tube was inserted into the antrum. A single strip of ribbon gauze was passed up the nose into the pituitary fossa.

*After-treatment.*—Urotropin was continued for a week. The antral tube, changed daily, was discontinued after five days. The nasal wick was continued for ten days. Once daily the cavities were gently irrigated with hydrarg. binod., 1 in 2000; on the ninth day, when it was judged that a protective granulation barrier would have formed, this lotion was preceded by hydrogen peroxide. After two weeks the only local treatment was an alkaline wash twice a day.

*Abstract of Dr. Wyatt Wingrave's report.*—The cells composing the fragments resemble those of the pituitary body individually, but are not grouped like them. The cells seen are grouped irregularly, and so are strongly suggestive of a neoplasm. Only in one place are the cells arranged in typical columns. Seen under 112 oil-immersion lens, certain intracellular copper-coloured granules show that the endothelium of the cell columns is neoplastic. Examples of hetero-mitosis, such as are usually seen in malignant

epithelioma, are extremely scarce; moreover, epithelioma is excluded by the absence of paranuclei. The absence of granulation tissue excludes sphenoidal cell disease. The section resembles the anterior lobe of the pituitary gland, but with an endothelioma.

#### After-history.

The temperature was normal or subnormal, and pulse averaging 80-90 after the twelfth day. The external strabismus persisted. Epiphora was present, but only intermittent and of slight degree; presumably the upper part of the nasal duct is open into the naso-antral cavity. There has been no conjunctival chemosis or infra-orbital oedema. The general condition was brighter, more alert. For five days patient complained of a trickling of fluid (? cerebro-spinal) into her mouth, but it was not possible to obtain any of this for examination. For two days she vomited about once hourly clear greenish fluid; the vomiting continued, with gradually abating frequency, for nearly a week. This duration made it improbable that the anæsthetic was the cause. Possibly the urotropin, which was continued for a week after operation, was responsible; but vomiting was a feature of her condition long before her operation. The gastric irritability prevented her from retaining sugar when given by the mouth to test her sugar tolerance. And even when spontaneous vomiting had ceased she would not retain sugar, even when heavily flavoured. She was allowed out of bed on the eighteenth day.

Headache has been entirely absent since the operation. The only sensation she complained of was hyperæsthesia of the scalp, which disappeared with the removal of the bandage. Patient had anosmia. (N.B.—The right nasal cavities were not touched at operation.)

#### Vision.

Rough tests made during the days following operation showed that with the temporal side of her left retina (nasal side of field) she could see as follows: fingers on the first day; type  $\frac{1}{2}$  in. high at 2½ ft. on the third day; type  $\frac{1}{8}$  in. high at the same distance on the fifth day.

On March 22nd (fourteenth day) Dr. Hawthorne reported as follows:—"Pupil reactions: R., normal; L., sluggish. No change in either disc. No post-operative oedema of discs. Vision: R., 6/12; L., 6/36. Test type read R., J. 1 slowly, J. 2 easily; L., J. 14."

*Visual fields.*—See charts; for convenience of comparison with the former record, the perimetric tracing already given under notes of Sept. 18th, 1917, is reproduced as a black line. The extent of the fields during the period preceding the decompression operation was not charted, because there was on the left no field to chart; at this time the raised intracranial pressure was shown by the headache also. (See Dr. Hawthorne's notes of June, 1918, and Feb. 22nd, 1919, when the vision on the left side is recorded as only perception of light.) The anosmia persisted.

On March 29th (twenty-first day) the sense of smell had been present during the last 48 hours. She was much brighter. No change in optic discs or in divergent squint. There was no return of the diplopia from which she had suffered in 1917, before her sight failed. Vision:—R., 6/9, L., 6/36; one letter 6/24. Type read: R., J. 1 slowly, J. 2 easily; L., J. 10.

*Visual fields.*—See charts on which the earlier tracings have been superimposed.

*Dr. Hawthorne's notes.*—April 2nd.—Blood pressure: systolic, 100 mm.; diastolic, 80 mm. Visual fields not materially affected. Discs as before. Vision: L., 6/24, three letters. Type: R., J. 1; L., J. 10. April 3rd.—Yesterday patient was out on the verandah; to-day she has what she describes as a bilious attack. The inner canthi and the region just below it are oedematous and a little red, for the first time (? dacryocystitis). T., 100·8° F. April 15th.—Pyrexia (April 3rd) subsided next day. Oedema at inner canthus has subsided. Sugar tolerance tested as follows: April 13th, 7 P.M., sugar 3iii. given. Urine tested at 11 P.M., and again at 8 A.M. on April 14th. No glycosuria. April 16th.—Discs, I.S.Q. Vision: R., 6/9; L., 6/18. Type: R., J. 1; L., J. 6. Perimeter (vide charts). To discard eye-shield or dressings. April 21st.—No more photophobia. June 4th.—Her husband writes: "..... her health is excellent. She is a totally different woman, and improves each day."

## Clinical Notes :

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### THREE UNCOMMON ABDOMINAL CASES ILLUSTRATING SOME PITFALLS.

By NORMAN C. LAKE, M.D., M.S. LOND., F.R.C.S. ENG.,  
MAJOR, R.A.M.C.;

AND

H. K. KEVIN, L.R.C.P. & S. IREL.,  
CAPTAIN, R.A.M.C.

THE following cases occurred within a short period at the Prisoners of War Hospital, Oswestry. They are recorded because of their rarity, and also indicate some pitfalls.

#### *Traumatic Diaphragmatic Hernia.*

CASE 1.—German prisoner of war, aged 20. Wounded Sept. 27th, 1918; admitted to this hospital Oct. 5th, 1918, with gunshot wound of left side of chest. Small entry mark in fourth interspace about 3 inches from mid-line; bullet felt subcutaneously just mesial to inferior angle of scapula. His field-card recorded hæmoptysis for a few days in France. Upon admission the entry wound was a mere scar; no hæmoptysis or pathological sign in the chest. On Dec. 11th he was up and due for discharge, but returned to bed complaining of pain in the left hypochondrium and constipation; he vomited once after food. No pathological lesion detected; general appearance and condition good. The following morning he was rather collapsed; abdomen considerably distended. The pain in the left hypochondrium continued; also tenderness present. Temperature 95.2° F., pulse 120; tongue dry and furred. The left chest was abnormally resonant and the heart dullness obscured. Two enemæ were given without result. Provisional diagnosis was intestinal obstruction, probably due to band in splenic region.

*Operation.*—Anæsthesia was very difficult owing to the rapidly increasing dyspnoea. Abdomen was opened in mid-line as rapidly as possible with a view to relieving this. The distended intestines were allowed to come out of the wound. No relief to respiratory embarrassment. The transverse colon was enormously distended; the obstruction obviously lay somewhere in the region of the splenic flexure which could be felt drawn up under the left dome of the diaphragm. At this point respiration ceased entirely; all the usual means of resuscitation were employed with no response.

*Autopsy.*—An aperture was found in the tendinous portion of the diaphragm on the left side, admitting four fingers; a considerable coil of the splenic flexure of the colon had passed through the opening. Strangulation had occurred at the sharp edge of the aperture. The bowel occupied practically the whole left side of the thorax; lung was compressed to a small mass on inner aspect and heart displaced well to right.

The bullet in its passage had passed tangentially across the dome of the diaphragm. The scar so formed had healed only to yield later when the intra-abdominal pressure was raised by exertion.

#### *Internal Hæmorrhage from Splenic Infarct.*

CASE 2.—German prisoner of war, aged 24. Admitted to this hospital on Sept. 28th, 1918, with diagnosis of nephritis. Upon admission the urine contained a small quantity of albumin, trace of blood, no casts. The heart was enlarged; soft organic systolic bruit at apex. A little œdema was present, distributed generally over the body. He was treated for nephritis; not much improvement. On Dec. 3rd and 4th he complained of pain in the left hypochondrium associated with tenderness. The following day he suddenly became blanched, the pain meanwhile increasing, the pulse very rapid and thin; temperature subnormal. Shifting dullness in the flanks more marked on the left side was noted. A diagnosis of internal hæmorrhage from the spleen was made; cause doubtful. Two or three old and recent pinpoint hæmorrhages in the conjunctivæ were noted; retinæ normal.

*Operation.*—When the patient reached the operating theatre his general condition was so bad that it was decided to transfuse him before operation. Saline infusion was immediately undertaken and a donor found. Rather over a pint of blood was transfused by the citrate method, the biological test being used for incompatibility. The patient improved somewhat, and as it is in our experience better to wait a short time after transfusion before anæsthesia, the operation was delayed. He was, however, obviously still bleeding rapidly and died before operation could be undertaken.

*Autopsy.*—General subcutaneous œdema. The heart was very enlarged; aortic and mitral valves sclerosed and on the surface many old and recent vegetations. Both lungs were œdematous. The peritoneum contained a large quantity of partially coagulated blood. One-third of the spleen had been converted into a large infarct extending back to the vessels in the hilum. Under the capsule, which had ruptured at one spot, was a fairly recent mass of blood clot; hæmorrhage was proceeding directly from aperture in splenic artery. The kidneys were "flea-bitten" and the mucosa of stomach and intestines showed similar points of hæmorrhage.

The case was obviously one of infective endocarditis, with an infected infarct in the spleen which had ulcerated its way through the wall of the splenic artery.

#### *Acute Idiopathic Dilatation of the Stomach.*

CASE 3.—German prisoner of war, aged 25. Admitted to this hospital on Feb. 3rd, 1919, with diagnosis of "acute abdomen." On the previous day after a midday dinner he was seized with a sudden pain in the epigastrium and shortly afterwards vomited. This seemed to give some relief and the case was not thought serious until the following morning, when he began to develop signs of peritonitis. No gastric history. Upon admission the condition was serious. He was continuously vomiting large quantities of slightly blood-stained material containing recognisable undigested food from the previous day. The abdomen was considerably distended, but at the same time quite rigid. There were shifting dullness in the flanks and tympanitic resonance over the front. The case was anomalous, but a diagnosis of peritonitis, probably due to perforation of a pyloric ulcer, was made and operation immediately undertaken.

*Operation.*—Abdomen opened in mid-line. The peritoneal cavity contained a large quantity of blood-stained, thin, purulent fluid. The stomach was enormously distended, occupying the greater portion of the whole abdomen; small intestines collapsed and pushed well down into pelvis. Stomach wall was thin and in places hæmorrhagic; no perforation found. A gastrostomy was performed by the Kader method and several pints of stomach contents were drained off. A large tube was inserted down to the duodenal region and another into the pelvis. The abdomen was sewn up, subcutaneous saline administered, and pituitary extract in 5 m. doses every three hours. The gastrostomy tube drained large quantities of increasingly blood-stained material. Death 17 hours after operation.

*Autopsy.*—The peritoneum contained some blood-stained fluid. The stomach was smaller than at operation, but its walls were so thin in places as to be quite transparent. The mucosa for the most part was deeply hæmorrhagic. The distension involved the first and second portions of duodenum; otherwise intestines were normal. No perforation or stricture; all other organs quite normal macroscopically.

The case fits in with the description of acute idiopathic dilatation of the stomach, usually a post-operative complication. In addition we here have a peritonitis most marked about the stomach. There are two possibilities: 1. That the peritonitis is the primary cause and the dilatation a secondary paralytic one. 2. That the dilatation is primary and the peritonitis due to the migration of organisms through the attenuated stomach wall. The man had been eating salted herrings; large masses of the sharp vertebral spines were found in the cæcum, the spines being so sharp as to perforate the bowel wall on the slightest pressure. The suggestion arises that infection may have been carried through the stomach wall in this manner, but the peritoneum usually deals very effectively with small infections of this nature. The case must, therefore, be left under the heading idiopathic.

We have to thank Lieutenant-Colonel R. Turner, R.A.M.C., for permission to publish these cases.

#### A CASE OF MULTIPLE OSTEOMATA OF THE SKULL BONES.

By C. N. SLANEY, M.R.C.S., L.R.C.P.

THE following case is recorded on account of the comparative rarity of the condition.

#### *Account of Case.*

The patient, aged 40, destitute of relations and having no recollection of his parents, mentally approximates to the cerebration of a child barely a quarter of his own age. To the best of his recollection, in 1888, when about 12, he sustained a blow on the right lower jaw from a cricket-bat; three months later he noticed a swelling (see figures, 1). This gradually increased in size, was painless, and unaccompanied

by any objective symptoms except for a sensation of cramp when he drank anything cold. This tumour was subsequently removed by operation. No evidence of fracture; right ramus of lower jaw was much thickened. In 1890 a similar small tumour (2) appeared over the left superior maxilla, attributed to a blow by a stone. It was followed in 1893 by a painless swelling (3) in the left lower jaw; no trauma. The fourth tumour developed gradually in 1895, a few months after his discharge from hospital; no trauma.

Multiple osteomata of skull bones.

Tumour 5, also in 1895, he attributes to knocking his head against a wall; it became gradually larger in size, but is now stationary. Probably the condition of the right eye is due to a tumour (6) similar to the others; no injury. He does not know when his eye trouble commenced, possibly in 1888; his vision was defective when he attended school that year. The bony outgrowths are in lower jaw bilateral. As a whole they give rise to no harmful pressure symptoms except in reference to the right eyeball.

The patient appears well nourished, is 5 ft. 1 in. in height, and weighs 109 lb. There is complete nasal obstruction, apparently due to a general swelling and turgescence of the nasal mucosa; also slight pharyngitis and hoarseness of voice. He professes to see best with a -12 D. sphere, but he prefers not to use glasses. The right pupil reacts to light and accommodation; left pupil dilated and fixed. With the margins of the orbits appearing normal, there is a small hard, movable tumour to be felt under the right upper eyelid, probably in relation with the lacrimal gland. The tissues of both upper eyelids are abnormally flaccid and overlap the cornea; an appreciable amount of the sclerotic is visible below each cornea, more marked in right eye; lacrymation is continuous. Proptosis of the right eyeball has been present since 1888; vision in both eyes more defective since 1894 and still getting worse. Some increase of tension in right eye; no apparent narrowing of visual fields. Media in both eyes hazy from muscae volitantes; discs and vessels smaller than usual. There are signs of old keratitis; positive Wassermann. His abdomen is protuberant and thorax rickety. There is marked indrawing of the skin with each heart-beat at its apex, apparently situated at left side of xiphisternal notch immediately below sixth costal cartilage. No dullness to right of sternum. His cranial nerves appear healthy except for loss of sense of smell. The angle of the mouth on the left side is drawn up, and he is unable to whistle. The left knee-jerk is absent.

#### Description of Tumours.

On examination of the several tumours the following points are observed:—

1. There is a linear operation scar 9 cm. in length along the lower margin of the mandible on right side from angle of jaw to symphysis; this scar is adherent in places to the underlying bone. The inner aspect of the lower jaw is smooth and regular, and appears normal on both sides; the

lower margin of the right mandible appears roughened, probably as a result of the operation. The alveoli and teeth are normal in position and regular in line; enlarged lymphatic glands in submental and submaxillary regions. The outer aspect of the lower jaw appears normal on the right side from the symphysis to tumour 4. No signs of recurrence. This tumour was stony hard.

2. There is a faint linear vertical operation scar on left side of nose about 1.5 cm. in length; also on the superior maxillary bone at this site a slight prominence, neither painful nor tender, but hard and bony.

3. This tumour extends from 1 cm. from symphysis to within 2 cm. of angle of left jaw. It envelops the lower margin of the mandible and extends upwards to just above a horizontal line level with angle of mouth. It is painless, hard, irregular in outline, circumscribed, and sharply defined; skin not adherent; it moves with the jaw and does not interfere with deglutition; no impediment to free movements of mandible. Observed from inside the mouth there is the appearance of a hard tumour growing from the outer plate of the mandible below the alveolar margin; there is no so-called expansion of the bone, but a tendency to fullness is noted over the upper part of the vertical ramus in the region of the parotid gland, but this fullness is not bony in character. He believes that this tumour is increasing in size.

4. This tumour extends from 4.5 cm. behind the angle of the right jaw to within 6.5 cm. of the symphysis; it does not envelop the lower margin of the bone, but extends up to the zygomatic arch; it is well defined, both anteriorly and posteriorly and at its lower margin, but seems to shelve off into the surrounding tissues at its upper part. It is hard, irregular in outline, and the margin of the lower jaw with its angle can be felt below the tumour, which has the appearance of growing from the outer plate of the bone below the alveolar margin, more or less in an upward and backward direction. The tumour moves with the jaw and the skin is not involved. He believes also that this tumour is increasing in size.

5. The tumour resembles those mentioned, is hard and bony, and painless. It appears as a circumscribed irregular swelling on the left side of the frontal bone 3 cm. above the orbital process; it is conical in shape, with its apex projecting upwards, outwards, and backwards, resembling a horn 3 cm. in diameter and 1.25 cm. in height. This tumour is stationary in growth, he thinks.

Parkhurst, I.W.

### A CASE OF CONGENITAL MULTIPLE SARCOMATOSIS.

By J. A. PERCIVAL PERERA, L.R.C.P., M.R.C.S.,  
LATE SENIOR HOUSE SURGEON, CHILDREN'S HOSPITAL, SHEFFIELD.

THE following case is of interest, on account both of its rarity and of the wide dissemination of secondary growths.

The patient, a full-term male baby a fortnight old, was admitted into the Sheffield Children's Hospital, under the care of Dr. H. Leader. Multiple rounded and nodulated tumours were scattered throughout the body—e.g., head,

Case of congenital multiple sarcomatosis.

thorax, abdomen, upper and lower extremities. These tumours, present from birth, were of varying sizes, from 1 x 1 x 0.5 cm. to 4 x 5 x 1 cm. There was superficial ulceration in the larger tumours; one or two on cheek and legs had started to fungate. The consistence ranged from jelly-like softness in the more superficial ones to more or less bony hardness in ones attached to the long bones, ribs, and skull.

The child weighed 10 lb. on admission, and was well nourished. He was then suffering from diarrhoea and also

bronchitis. Large masses, presumably enlarged mesenteric glands, were felt plainly in the abdomen. After a fortnight the child died. I did a post mortem on it and made the following report.

*External appearance.*—A well-nourished male baby weighing 9 lb. Numerous rounded tumour-like masses varying in size from  $0.5 \times 1 \times 0.5$  cm. to  $4 \times 5 \times 2$  cm. scattered throughout the body. The tumours seemed to arise from different layers of the body in different places—e.g., some from skin, some from connective tissue, some from muscles and their tendons, and some from periosteum. Many of the tumours, especially the larger ones and those where pressure had been brought to bear by the weight of the body, were ulcerated.

*Internal examination.*—Scalp and skull: Numerous rounded growths,  $2 \times 3 \times 1$  cm., ulcerating through the scalp and attached to the diploë of the skull. Apparently non-capsulated. Brain and meninges: Normal. Thorax: Thymus gland normal. Mediastinal glands matted together, very hard to the touch, and very much enlarged. Pericardium: The parietal layer contains one or two hard rounded nodules,  $2 \times 1 \times 0.5$  mm., not extending to inner wall. Heart: Normal. The ribs and vertebrae were studded with tumour-like growths apparently coming from the periosteum. Abdomen: Liver: Several nodules  $2 \times 3 \times 1.5$  cm. Spleen: Three nodules of various sizes. Right kidney: One nodule at lower pole. Left kidney: Normal. The retroperitoneal and mesenteric glands matted together into groups; very hard and in places as large as billiard balls.

Microscopic examination of sections cut from different organs and done at the Sheffield University, revealed small round-celled sarcoma.

It was quite impossible for me to say where the primary growth started. It is possible it started as a periosteal sarcoma of one of the bones and rapidly spread throughout the body by metastases.

As to family history, father and mother are healthy, this being their first child.

I am indebted to Dr. Leader for permission to publish this case.

#### A CASE OF CIRROID ANEURYSM OF PALM OF HAND.

By J. TODESCO, M.R.C.S., L.R.C.P., D.P.H. ENG.

THE following case appears uncommon, as there was no history of trauma or other cause to explain the condition.

The patient, a woman, aged 58 years, was admitted to the West London Hospital on April 8th, 1919, with the history that she had first noticed a swelling over the palm of her right hand 20 years ago. During that period it had broken down on several occasions, with discharge of pure blood. The bleeding had never been severe, and she had been able to do her house-work. For the last ten weeks a similar swelling had appeared on the palmar aspect of the right hand over the terminal phalanx of the middle finger; this had broken down and become septic. (See figure.)

The patient said that both the swellings over palm of her right hand and over middle finger had been painless, but since the latter had broken down she complained of a dull burning sensation in her hand. She was married, with four children; had had no miscarriages. The Wassermann reaction was negative; no bony changes by X ray; both arms were equal in length.

Cirroid aneurysm of palm of hand.

On examination, there was a rounded tortuous pulsating tumour over centre of the palm of the right hand, with some scarring of the skin near the base of the middle finger. The distal and middle phalanges of this digit were gangrenous. There was also some swelling with "mottling of skin" (which was unbroken) over the two distal phalanges of the right ring finger; and some engorgement of veins of forearm: On compressing the arteries at the wrist the swelling over the palm got smaller, but on releasing pressure it swelled out again. On auscultation a distinct "souffle" was heard over the palm, being conducted both upwards along the proximal phalanges of middle finger and downwards towards wrist.

Owing to spreading sepsis and pain the third finger was amputated on April 24th at the metacarpophalangeal joint.

My thanks are due to Lieutenant-Colonel Donald Armour, R.A.M.C., under whose care the patient had been, for permission to record this case, and to Sister Wilks, in charge of the X ray department, for the photograph.

## Medical Societies.

### ROYAL INSTITUTE OF PUBLIC HEALTH: LONDON CONFERENCE.

COMMENCING on June 25th the Royal Institute of Public Health held at the Guildhall a conference, in which the chief aspects of public health—the work of the new Ministry, the prevention and arrest of venereal disease, housing in relation to national health, maternity and child welfare, and the tuberculosis problem—were separately and fully discussed, the debates culminating in a series of resolutions which focussed the present position in regard to these problems. The inaugural meeting took place at the Mansion House, under the direction of the LORD MAYOR, who was supported by His Majesty King MANUEL, Earl BEAUCHAMP, Viscount KNUTSFORD, Lord WILLOUGHBY DE BROKE, Lord LEVERHULME, and others.

#### *The Lord Mayor's Speech.*

THE LORD MAYOR made a graceful reference to the imminence of peace, and to the generosity of Lord Leverhulme which had resulted in the Institute being well supplied with technical equipment, thus enabling it successfully to carry on during the trying time of the war. The Institute was also to be congratulated on at length seeing established that Ministry of Health which it had continuously advocated since it was first urged at the Dublin Conference in 1892. The fine work done by the Institute in the 30 years of its existence strengthened its case for endowment, especially now that there was a greatly increased activity in all that concerned the nation's health.

#### *The Need for a Permanent Endowment for Research Work.*

LORD LEVERHULME announced a donation of £100 from the King and a generous cheque from the Prince of Wales. Good health, he said, was at the very foundation of a large and profitable output. In order to carry out necessary research work in public health matters it was essential that the Institute should have a permanent endowment, and he earnestly appealed for financial support to that end. One of the objects was to found a national journal of preventive medicine, and for such a good programme as the Institute had set itself he thought there was a good case for a substantial Government grant. He had always been much impressed by the Institute's economy of management and efficiency of service, and he was certain the money received would be wisely expended. £30,000 was the sum asked for, and he proposed a resolution urging the Government to make a grant towards this amount.

H.M. King MANUEL (an honorary Fellow of the Institute), in seconding the resolution, said that everything which could now be done for the improvement of public health would be of the utmost importance. We had recently been living in times when brains, money, and everything we possessed were used for purposes of destruction; let the people now do likewise in the work of reconstruction. The one thing which above everything else won the war was the health of the country. In conclusion, His Majesty trusted that the knowledge gained in dealing with the men disabled in the war would be applied to the case of the civilian population.

Lord BEAUCHAMP, who was President of the Berlin Conference before the war, said we could not expect satisfactorily to deal with the reconstruction of the national life unless the standard of health of the community became higher than in the past; and he hoped the Government would suitably recognise the University work being done by the Institute in preparing students for degrees in public health.

Lord WILLOUGHBY DE BROKE also supported the resolution. He said the need was to bring to maturity as many British boys and girls as possible, and rear them in such surroundings, and with such knowledge of the fundamental laws of health as would enable them to promote national efficiency in the highest degree. In hoping for the Ministry of Health a great and increasing success he pleaded for a universal grasp of the leading facts of science, which was a fundamental necessity to the full power of the race.

Further support came from Sir THOMAS OLIVER and the Director of the Medical Department of the Navy, the DEAN of ST. PAUL'S, and Lord KNUTSFORD. Dr. J. UTTING (Liverpool) objected to the part of the resolution which asked for a Government subsidy, as it would mean, in his opinion, that the Institute would be under the "blighting influence of bureaucratic control."

The resolution was carried.

On the proposition of the BISHOP of HEREFORD, seconded by Dr. MARY SCHARLIEB, the Lord Mayor was cordially thanked for his hospitality.

#### I. THE WORK OF THE MINISTRY OF HEALTH.

Dr. W. R. SMITH (Sheriff of the City) presided at this session. He said it was difficult to exaggerate the far-reaching importance of training men and women to take up public health work. The school medical service originated with the School Board for London, and it was now a great satisfaction to find Sir George Newman, late medical officer to the Board of Education, attached to the new Health Ministry. Many health measures owed their origin to special efforts for local application only, efforts promoted by a Health Committee of some large municipality. This was the case with such measures as the Infectious Diseases Notification Act, that for the notification of tuberculosis, the Notification of Births Acts, while other measures dealt with town planning, a pure milk-supply, milk for mothers unable to suckle their children, &c. He hoped the new Ministry would not put into operation any schemes which would destroy or impair the usefulness of such bodies. He thought adequate support for research should be forthcoming from the Treasury, and those intended for conducting research should receive careful training to that end. They needed to have not only a scientific training, but patience, an analytical mind, and sound judgment. He pointed out that great powers were possible to the new Ministry through the channel of the Orders in Council that the Act provided for, which Orders became operative if no opposition came from either House within 30 days.

Sir H. KINGSLEY WOOD, M.P., spoke at some length on

#### *The Central Organisation of the Health Ministry.*

He hoped that the Consultative Councils would receive the benefit of the long experience of the Institute of Public Health. He thought that in former days and up till very recently the preventive aspect of public health had been almost entirely lost sight of; the problem had never been adequately tackled as a whole, but had rather been approached by jerks, stimulated in many cases by the menace of an epidemic or pestilence. He agreed there had been in this country an utterly inadequate provision for research, a beggarly £60,000 a year being the sum expended on it. A Medical Research Department was one of the equipments of the new Ministry, and this would be under the direction of the Privy Council; nothing short of this was adequate for a matter of such world-wide importance, for its activities would embrace the whole of the British Empire, with branches in every part. One of the most serious indictments against our health conditions had been that we had, to a large extent, taken a parochial instead of a national view of health affairs, and that view had been guided too much by considerations as to rate increases. For that he considered the Government were largely to blame, as they had not given sufficient grants to local authorities to enable them to carry on their work. Until the formation of the Health Ministry, 21 Government departments or sections were dealing with health affairs. There were a large number of

laggard authorities which needed to be stirred up to the adoption of the modern spirit in administrative affairs. He paid a tribute to the memory of Lord Rhondda, who did so much to bring about what all were so pleased to see established. With regard to tuberculosis, the employed class was entitled to such provision as had been made for sanatorium benefit, but a large mass of people had no right and no access to the same treatment. Many thousands of pounds were being spent in connexion with this disease, of which, he thought, about 75 per cent. was thrown away.

Dr. F. E. FREMANTLE (consulting medical officer for Herts) discussed the question of

#### *Local Administration in Health Matters.*

He had drawn much help from experience of military hospitals during the war; in civil work, however, considerable latitude must be allowed. The ultimate centre of the whole activity was the family life. Under the new Ministry health in the factory was left out at present, but he hoped it would soon be included. But little had been done as yet in the matter of national assistance for the poor professional and commercial classes. He urged that there should be one authority, out of which the separate activities should be developed as the need for them arose. He believed in coöperation on central bodies of persons with special knowledge which would be useful to the community. Prevention and cure could not, in practice, be separated, therefore there should be one administrator for both. The essence of public health progress should be a sense of individual responsibility, and measures would be most effective of which the public had become convinced as to their necessity.

Dr. J. MIDDLETON MARTIN spoke of public health administration in Gloucestershire, of which he is county medical officer. He emphasised the serious factors of distance and sparse populations, and therefore the need of improved transport to secure prompt consultations.

Lady BARRETT, M.D., dealt with

#### *The Women's Aspect of the Work of the Ministry of Health.*

The speaker made a strong plea for efficient home administration. The unit of the local area was the home, and the administrator of the home was the woman. Housing schemes might be perfect, but unless the women in those houses had the knowledge and the willingness to use the facilities which had been planned for them, housing schemes would not make any appreciable difference in the health of the country. The same was true of infant welfare schemes; there must be women workers who had access to the homes, otherwise even the women who attended instruction might hear all that was said and yet go home without doing anything. All strong and irresistible habits were learned in infancy, and the necessary health habits could only be inculcated if the women had not only the knowledge but also the goodwill to do it. The people who at the moment had the greatest influence in the home were women of three skilled functions—nurses, midwives, and health visitors. These women, therefore, required careful representation in connexion with the Ministry of Health, because they knew the difficulties met with in the practical application of the various schemes. Men and women were working together for the good of the race; it was not a male race or a female race, but both, and therefore both should be combined for teaching and for administration.

In the further debate a large number took part, and the following resolutions were passed and ordered to be sent to the Ministry of Health:—

(1) That this Conference views with satisfaction the contemplated creation of Advisory Councils in connexion with the work of the Ministry of Health, and urges that the services of those who have had long, wide, and practical experience in administrative and executive public health should be secured upon those councils.

(2) That in view of the large national demands which will be made on the Ministry of Health as an organising and controlling centre it is desirable that it should not be burdened with functions and details which may result in depriving the local authorities of a sense of responsibility and a sense of initiative.

(3) That in the view of this meeting sanitary inspectors, health visitors, and similar classes of public health officials should be adequately trained, and that the present system of examinations should be coordinated so as to secure one qualifying examination for the whole country.

(4) That in view of the invaluable services rendered by women who are serving as elected or co-opted members upon local authorities, or as officials of such authorities, this Conference is of opinion that women should be included in larger numbers on all advisory bodies, and that greater facilities be provided for the training of expert women workers in the homes of the people.

(5) That in the opinion of this Conference all questions comprised within the scope of port and maritime sanitation should receive the earnest attention of the Ministry of Health, and in order to ensure greater co-operation and confidence between British and foreign port authorities, the widening and readjustment of the agreements reached at the International Sanitary Convention are necessary.

(6) That greater use should be made of the services of the British Consuls in foreign ports in obtaining and transmitting information relative to the sanitary condition of the ports.

(7) That it is desirable that smaller authorities should be joined together with the view of securing the whole time services of medical officers of health and other sanitary officials.

## II. THE PREVENTION AND ARREST OF VENEREAL DISEASE.

The chair at this session was occupied by Sir WILLIAM MILLIGAN (Manchester) in the absence of Lord Sydenham. The chairman reminded the audience of the initial step in a national movement against these diseases taken by Sir Malcolm Morris. He impressed upon the meeting the widespread prevalence of syphilis and gonorrhœa and the large number of cases going about to-day in an infective condition. He assumed that none of those present were anxious to see a revival of the "C.D." Acts; the measure had been tried in nearly every country on the globe, and practically every country had given it up or was about to. The subject must be approached from a different angle; the public must be educated and shown the dangers of the disease and the calamities which followed in its wake. The universities devoted too little attention to the teaching of this subject; so widespread a disease should be carefully taught to all medical students. Women must be properly paid for their work, thus removing temptation from the path of the poor self-supporting girl. He hoped to hear opinions as to whether compulsory notification was advisable, now or at any time. If adopted was it likely to act as a preventive measure? A very important question was that of prophylaxis; should it be encouraged by the profession? Further, should inmates of institutions who were suffering from these diseases be retained there until they were cured? The present methods of treating syphilis were complicated, and required considerable technical skill, and he thought the aim of syphilologists should be to secure some method of treatment which was somewhat more simple and easily applicable, so that it could be put into a greater number of hands. It was quite a mistake to regard gonorrhœa in the light-hearted way which many people did, and it would be useful for this gathering to express an opinion on this. He regarded gonorrhœa as almost as destructive as syphilis. The danger in the matter of spread was not the street-walker but the clandestine prostitute, who used this as a means of eking out her underpaid living. He doubted if gonorrhœa, especially among women, was ever cured. He hoped the discussion would be focussed on a resolution.

### *The Woman's Standpoint.*

Dr. MARY SCHARLIEB presented the subject from the woman's standpoint, which was, she said, in the estimation of the public, somewhat of a novelty because women and children had been supposed to know nothing of this evil. Those who did not know of an evil could not protect themselves against it, and it was unwise to keep women in ignorance of the troubles to which they might become victims. It was still more criminal for parents to neglect to teach their children to value and respect their bodies, and how to maintain their bodies in purity, temperance, and chastity. When parents were either unwilling or unable to discharge that sacred duty they should suitably delegate it to others, such as schoolmasters and schoolmistresses. Dr. Scharlieb proceeded to speak of these diseases as they affect pregnant women and children before and after birth. A considerable percentage of the 100,000 deaths of unborn children which occur every year were due to these diseases. In England and Wales something like 800,000 babies were born alive every year, and of them about 100,000 died before the anniversary of their birth was reached, many from syphilis which they derived from their mother before birth. 20,000 die within a week after birth. None of the ordinary causes of infantile mortality—bad air, bad food, bad milk, bad maternal management, whooping-cough, measles, bronchitis—were operative so soon after birth; the majority who died so early did so because they were born in a dying state, a heavy percentage owing this to infection with syphilis. It had been calculated that about 30 per cent. of all the blindness of the country, 30 per cent. of the deafness, 16 per cent. of the insanity, and most of the

feeble-mindedness was due to venereal disease. Gonorrhœa as it affected women was a loathsome ailment and a dangerous disease. Evidence was given before the Royal Commission on Venereal Diseases that one-half of the sterility of the country was due to gonorrhœa, and a distinguished medical witness attributed one-fourth of the serious pelvic conditions which needed a major operation to the same cause. Yet an Irish medical student, when asked how he would treat these diseases, replied, "With contempt." There were now very few large towns which had failed to provide clinics and schemes for treating these diseases, a wonderful progress in less than three years, and the speaker urged the members of this Conference to do their best to get the work enlarged.

### *The Civilian Standpoint.*

Sir MALCOLM MORRIS treated the subject from the civilian standpoint, which, he said, was a more complex one than that of the Army, for in the case of the latter, masses of men were under strict discipline and instruction, while the ordinary population consisted of men and women, young and adult, some of them not of high intelligence, and with but a rudimentary sense of responsibility; hence they did not seek advice until the disease was far advanced, and were apt to withdraw themselves from treatment as soon as the obvious symptoms were suppressed. He referred with satisfaction to the propaganda work which had been carried out by the National Council for Combating Venereal Diseases, particularly during the war, in lecturing to two million men. The most promising form of propaganda was through teachers, for no boy or girl should go out into the world ignorant of sex perils, or of the value of sexual continence. He referred to the poster and other propaganda work, and said that the giving effect to the Report of the Royal Commission by the Local Government Board was one of the brightest incidents in the public health administration of this country. There should be no area without facilities of ready access for the treatment of these diseases. Some thought the demobilised soldier was spreading the disease; others that the soldier was really the victim of the non-prostitute girl and woman who during the war had fallen into a loose mode of life. Relaxations of various kinds at the present time favoured a recrudescence of venereal disease, such as followed previous wars. Prophylaxis he did not regard as a wise, but as a panicky measure, though he preferred not to enter into the ethics of it. By supplying a man with a prophylactic outfit, he was released from the restraint which might otherwise have been operative; certainly it would not diminish a tendency to promiscuity. Dr. Otto May had resigned from the National Council because that body did not countenance prophylaxis in that way, but its policy was still maintained, for otherwise the great moral forces of the nation would be antagonised to the Council. He moved:—

That in the opinion of this Conference it is absolutely essential, alike from the military and civilian standpoints, including also the interests of women and children, that legislation affecting venereal disease should be amended and harmonised, so far as it possibly can be, with legislation affecting other forms of communicable disease, the aim being to ensure continuity of treatment and the prevention of the spread of infection.

Mr. E. B. TURNER seconded the resolution. He said he felt sure there would be set up some form of confidential notification of these diseases, which would ensure that most important desideratum, continuity of treatment, and treatment which was efficient and skilled. This meant the surmounting of very formidable obstacles. Very few doctors, owing to the sacredness of professional confidence, would voluntarily consent to notification, but if it became a statutory compulsory requirement he thought most would soon fall into line without trouble. Legislators must be shown the necessity for some such revision in the law. He concluded by an appeal to do all that was possible to stop the activities of the venereal quack by means of prosecutions.

### *Inadequacy of the Present Measures.*

Dr. J. H. SEQUEIRA, who has charge of the London Hospital Venereal Clinic, said he was convinced more and more that the measures adopted at present in combating these diseases were inadequate and cumbersome, as well as expensive in time and money. He described the course of treatment, and explained the need for early advice, regretfully remarking that 40 per cent. of those who attended the clinic did not complete the treatment, despite the organised

efforts to follow cases up and the emphasis laid upon the taking of the thorough course. From the scientific standpoint these diseases were among the easily preventable, and the natural question was, Why were not prophylactic measures more thoroughly carried out? The reason was a moral, not a scientific one. For a long time he was against prophylaxis in this matter for that reason, but he had had proof of such important results from prophylaxis, which he narrated, that, in view of the great prevalence of the diseases, he had changed his opinion, especially as he failed to differentiate ethically between supplying a man with a prophylactic outfit, and giving him an address to which he could go for so-called "early disinfection" after the risk had been run.

Sir THOMAS BARLOW said that until adequate national provision for treatment had been set up it was undesirable to lay down penal regulations regarding notification. The more treatment centres were set up, and the more a kindly and humane tone pervaded their administration, the more would sufferers avail themselves of these means of cure. He gave the results arrived at by Dr. F. H. Teale in regard to the antiseptic function of soap and water in the case of the gonococcus. Exposed to a 2 per cent. solution of ordinary yellow soap for two minutes, only a trace of growth remained, and when exposed for four minutes it gave no growth at all. Answering Dr. Sequeira, he urged a full consideration of the moral aspect, as sexual promiscuity had been one of the fatal deteriorating influences in civilisation, seen in the decay of the Roman Empire. A loose morality on this question tended to weaken the marriage bond and produce all its dangerous sequelæ. He urged strict cleanliness, especially after risk had been run, but not the supplying of a prophylactic packet.

Mrs. GOTTO said the question was really as to how to make the provisions for treatment available to a mixed general community in a way which would be helpful medically without being harmful socially. Social, medical, and ethical ideals converged into one, for she did not believe a real truth was ever divided.

#### *Methods of Diminishing Venereal Disease.*

Dr. OTTO MAY said that to diminish these diseases two lines of effort could be used—reducing the practice of sexual promiscuity, or making such promiscuity less dangerous. The standard of conduct at the present time was very low. Only 9 out of 100 officers between 19 and 24 years of age did not admit sexual experience with females, a fact which connoted an equally low standard in the other sex. If that was the case after thousands of years of ethical teaching, did it not suggest that there would not be much progress in this matter along that road? With the present delayed age of marriage there was possibility of some damage arising from enforced chastity; alienists knew that much functional nervous disease, even going on to homo-sexual manifestations, ensued on enforced chastity. He did not say this by way of apology or of an incentive to unchastity, but the question had to be faced. As to the dangers arising from promiscuity, physically much was possible in the way of prevention by disinfection; the chief difference of opinion was as to the nature of the disinfection to be employed. But he agreed with Dr. Sequeira in seeing no ethical difference between telling people where to receive absolution from the effects of misconduct and telling them where to get a package which would give them similar absolution. Hospitals could not be induced to remain open day and night in order to be ready to give the "early treatment" at all hours, and every hour of waiting increased the danger to the victim.

In the further full discussion Mrs. PALMER (Southampton) urged the straight view on this national question, putting aside all hypocrisy. Ordinary people had two powerful impulses, those of self-preservation and the exercise of the sexual function, and it was necessary to find out whether our system of society catered for both. Seeing the low standard of morality at present prevailing, we must not allow high ethics to prevent us using every means to stamp out venereal disease. What people seemed afraid of was having against them the organised force of the Church. It was grievous that to hold views favouring prophylaxis meant resignation from the Council for Combating Venereal Disease.

Mr. POWELL pleaded that life for all classes of people must be made fuller and sufficiently interesting; they should not feel that sexual intercourse was their only form of amusement.

The CHAIRMAN, in putting the resolution, said all were agreed as to the need for teaching biology to children, and the proper persons to do it were the father to the son, the mother to the daughter. But if they objected to do it another means must be open. He had written to the headmasters of every public school in England asking whether they gave instruction in sexual hygiene. The reply from almost every headmaster was, that when they found that the boy had not been told anything about it—which was almost universal—the headmaster took him for a walk or had him in his study on the eve of his departure from school and told him what was necessary. That was the next best to parental instruction.

The resolution was carried with two dissentients.

(To be continued.)

## THE MEDICO-LEGAL SOCIETY.

### *Annual Meeting: Election of Officers.*

THE annual general meeting of this society was held on June 24th at 11, Chandos-street, W., Sir W. J. COLLINS being in the chair.

Mr. R. Henslowe Wellington was elected President for the ensuing year; Sir J. Macdonell, Mr. A. H. Trevor, Dr. M. I. Finucane, Dr. W. H. Willcox, and Dr. F. G. Crookshank vice-presidents; Mr. E. Goddard and Dr. B. H. Spilsbury honorary secretaries.

The reports of Mr. WALTER SCHRÖDER, the honorary treasurer, and of the honorary secretaries were adopted.

The CHAIRMAN referred to the work done for the society, since its birth in 1901, by the President-elect (Mr. Henslowe Wellington) and alluded feelingly to the loss sustained during the last 12 months in the deaths of two successive Presidents, Sir Samuel Evans and Dr. F. J. Smith, in their terms of office.

At the conclusion of the business of the annual general meeting an address was given by Dr. LIONEL WEATHERLY, entitled—

### *"A Point of General Importance: The Interpretation of Secs. 47 and 321 (ii.) the Lunacy Act, 1890."*

Dr. Weatherly said that he would divide his address into three parts: (1) a preamble; (2) a story; (3) a moral. By way of preamble he alluded to the necessity for care, on the part of lawyers, in the drafting of Bills, particularly those concerning matters of medical importance; and he insisted on the necessity for the participation of medical interests when such Bills or Acts are in contemplation. His "story," which was narrated impersonally, referred to incidents which are already widely known, and was concerned with the events that followed the request made to a consultant in lunacy, by the relatives of a certified lunatic, to visit that person in a county asylum where he was actually a paying patient. Difficulties in obtaining the consent of the superintendent of the asylum to the proposed visit of the consultant were only overcome by the issue, under pressure, of an order for admission made by a Commissioner in Lunacy; but, although physical admission to the asylum and access to the patient were obtained, the consultant did not in the event secure either personal communication with any medical officer of the asylum or the opportunity of being informed, by a perusal of the records or otherwise, of the patient's case. Legal action was taken, on behalf of the patient's relatives, with a view to the overcoming of what was considered to be the intentional withholding of information necessary if the visit was to be other than a fertility; and it was submitted that, on a certain interpretation of Secs. 47 and 321 (ii.) of the Act of 1890, merely physical admission to the asylum and access to the patient was not a proper compliance with the order of the Board of Control. The action failed; it being held by Mr. Justice Darling that the order had been technically fulfilled, and that there was no power in the Board of Control to order the production of the records to an independent consultant visiting a patient at the request of the relatives.

Dr. Weatherly discussed the extent to which, in his opinion, this ruling was open to dispute, and urged the necessity in the interests of the insane for an alteration in the law, if, indeed, it has been correctly interpreted by Sir Charles Darling. Dr. Weatherly drew attention, moreover, to an early contention of the Board of Control during the progress of the events narrated, that such a proceeding as

the visit of an independent medical man to such a patient in a county asylum is "unprecedented"; and he emphasised the fact that it had been repeatedly stated (and there was nothing to show the contrary) that the action taken by the asylum superintendent, whilst seemingly of an obstructive nature, was in no sense personal and directed against the particular consultant engaged.

An important and interesting debate followed the address, in which Mr. GARDINER, Mr. HARVEY HARTLEY, Mr. GODDARD, Mr. HENSLOWE WELLINGTON, Dr. CROOKSHANK, and others took part.

#### *Summary of the Discussion.*

The CHAIRMAN, in summarising the discussion, said that he, an erstwhile chairman of the L.C.C. and a member of its Asylums Committee, certainly did not regard as "unprecedented" the admission of medical men to see asylum patients, and to inquire into various matters concerning them. But the question was one to be considered impersonally, and in discussing the purely legal aspects of the case he concluded by observing that there appeared to him good grounds for seeking amendment of the statute. In view of the representations made by the Medico-Legal Society in earlier years to successive Lord Chancellors in regard to death certification and coroner's law, he did not think it would be outside their province to make, if so disposed, similar representations in regard to this case also.

Dr. WEATHERLY briefly replied to various questions put to him, and thanked the society for the care and sympathetic interest with which the subject had been discussed.

## Reviews and Notices of Books.

*A Treatise on Orthopaedic Surgery.* By ROYAL WHITMAN, M.D., M.R.C.S. Eng., F.A.C.S., &c. Sixth edition, thoroughly revised. Illustrated with 767 engravings. London: Henry Kimpton. 1919. Pp. 914 + xii. 36s.

IN the preface to the sixth edition of this well-known work Dr. Royal Whitman instances the recent severe epidemic of anterior poliomyelitis in New York and its vicinity and the crippling accidents of war as two factors which have definitely established the place of orthopaedic surgery in the popular mind. But it is, as he says, rather the constant purpose of this specialty to prevent and correct deformity and to preserve and restore function which governs treatment from beginning to end, and is its chief distinction. It is not necessary to dwell upon the merits of this well-known text-book. Suffice it to say that it has kept well up to date. But the final chapter on military orthopaedics, the addition of which distinguishes this edition, calls for some comment. This chapter reminds us that the military authorities of the United States were able to make use of the Allies' experience and that they paid great attention to the examination and preparation of recruits. In this work orthopaedic surgeons took a large share. The primary examination decided whether a recruit should be unconditionally accepted or rejected, or if he should be conditionally accepted as fit for certain duties, but not for all the strains of active service. Under the rules of the selective service governing orthopaedic disabilities these conditional cases and many of the recruits who broke down under training were treated in special training-camps, where they were divided into groups according to the character and degree of their disability and drilled under the supervision of orthopaedic surgeons. Strains of the back and weak and disabled feet were the commonest disabilities.

The regimen in these camps was severe and calculated to discourage all malingering. Dr. Whitman lays great stress on the importance of eversion of the front of the foot as indicative of weakness. The normally low-arched foot is not thus everted and is generally quite fit for the strains put upon it. Weak and flat feet appear to be the bane of the citizens of the United States, and hence far more is heard of these disorders in military orthopaedic work there than in this country. Dr. Whitman makes the interesting statement that although strain or discomfort in the back is noted in about 25 per cent. of the recruits, in most instances it is relieved by the military drill and by the posture enforced by carrying the pack.

The treatment of fractures, of nerve injuries, and the preparation of amputation stumps are adequately dealt with, but call for no remark. They embody the conclusions to which four years of war have led most surgeons. A useful section is that on Attitudes of Election, in which the standard position in which an ankylosed joint is most useful is considered for all the chief articulations. We note that Dr. Whitman favours full extension as the position of election for an ankylosed knee, therein differing from Lieutenant-Colonel Brackett, the Director of Orthopaedic Surgery in the United States Army, who much prefers an angle of 135°. Sir Robert Jones, and many other experienced surgeons, however, agree with Dr. Whitman, whose opinion appears to us to be a sound one.

A short but useful section on Reconstructive Treatment concludes the chapter and the book.

*Nerve Injuries and their Treatment.* By Sir JAMES PURVES STEWART, K.C.M.G., C.B., M.D., F.R.C.P., Senior Physician to the Westminster Hospital, &c.; and ARTHUR EVANS, M.S., M.B., F.R.C.S., Surgeon and Lecturer on Surgery at the Westminster Hospital, &c. Second edition, revised and enlarged. London: Henry Frowde and Hodder and Stoughton. 1919. Pp. 250. 12s. 6d.

WE reviewed this book favourably on its first appearance. In its new edition it is increased in size by some 40 pages and contains considerably more illustrative instances of lesions of the various peripheral and cranial nerves. The authors have seen in all some 520 cases of nerve lesion, and they have marshalled their facts in a logical and readable way. The photographs and diagrams number some 40 more than in the original edition. In its present form the book is sure of appreciation by neurologist and practitioner alike.

*General Medicine: Practical Medicine Series.* Vol. I. Edited by FRANK BILLINGS, M.S., M.D. Chicago: The Year Book Publishers. 1919. Pp. 622. \$2.50.

THIS volume is the first of a series of eight, each on different aspects of medicine, published at intervals throughout the year, and each reviewing 12 months' original work on the subject with which it deals. The first volume on general medicine covers considerable ground, and includes abstracts from papers on such rare diseases as lipodystrophia progressiva. We find no reference here to the work of Dr. Lewis on the effort syndrome. Possibly this is not considered to come within the range of general medicine. The work is classified into various sections. That on tuberculosis may be taken as a fair sample of the quality of the whole volume. It contains no striking papers, but some are worth careful study, especially those on errors in diagnosis (p. 25) and Roentgen ray diagnosis of pulmonary tuberculosis (pp. 27 and 29), and on clinical experience with Koga's cyanocuprol (p. 59). The others deal with a variety of subjects, including nomenclature, system of examination, lung reflexes, artificial pneumothorax treatment, tobacco-smoking, gastro-intestinal disorder, the tuberculous soldier, and prognosis. Writing on the last Dr. Fishberg omits to emphasise the prognostic value of progressive fibrosis, and in the paper on a system of examination no mention is made of the importance of determining the position of the heart and the area of superficial cardiac dullness.

The articles seem to be abstracted almost entirely from British and American journals, from which practitioners without knowledge of foreign tongues can make abstracts for themselves, but it is clear that many will not have time or desire to do so.

*Irish Ethno-Botany and the Evolution of Medicine in Ireland.* By MICHAEL F. MOLONEY, M.B., Ch.B. N.U.I. Dublin: M. H. Gill and Son, Ltd. 1919. Pp. 96. 4s. 6d.

Dr. Moloney tells us in his preface that his book "aims to give in outline the evolution of medicine in Ireland, and to indicate the comprehensive character of Irish ethno-botany." The outline is exceedingly sketchy and we cannot see, so far as this book is concerned, that Irish folk-botany differs much from the folk-botany of England, Scotland, or Wales. Those who are acquainted with the FitzPatrick lectures of the late Dr. Frank Payne or those of Sir Norman Moore will find that very many of the medicinal uses of plants given by Dr. Moloney are also given by the two writers just cited. For instance, Yarrow—i.e., *Achillea Millefolium*—is stated on p. 29 by Dr. Moloney to

have been used as a cure for toothache. The same use of the same drug appears in the Anglo-Saxon translation of the Herbarium of Apuleius, quoted by Dr. Payne in his "English Medicine in the Anglo-Saxon Times." Again, Dr. Moloney gives an old Irish saying about salvia, which he translates as follows: "While the sage is on the mountain no one should die." In the well-known poem of the School of Salerno, *Regimen Sanitatis*, written about 1100 A.D., we find the following: "Cur moriatur homo cui crescit salvia in horto?" though with great good sense the writer gives the answer, "Contra vim mortis non est medicamen in hortis." On p. 44, Dr. Moloney says that saffron is used by the country people to-day "to bring out the rash of measles." This use is not confined to Ireland, for saffron tea is a common English rural remedy for measles even to the present day. Dr. Moloney gives a very full list of plants used in native Irish materia medica, but only in a very few instances does he say for what complaints the various preparations are used. As to Part II. of his book, which is called "History of Medicine in Ireland," it is so slight as to be of little value. The best features of the book are the indices, of which there are three, in Erse, English, and Latin respectively.

*Nerves of the Human Body.* By CHARLES R. WHITTAKER. F.R.C.S. Edin., Senior Demonstrator of Anatomy, Surgeon's Hall, Edinburgh. Second edition, revised and enlarged, with plates. Edinburgh: E. and S. Livingstone. 1919. Pp. 76. 3s. 6d.

Mr. Whittaker's edition of the late Professor A. W. Hughes's "Handbook on the Nerves of the Body" belongs to the *multum in parvo* type of text-book, for it is little more than a catalogue of the peripheral and cranial nerves and sympathetic system. So far as it goes it contains a practical compendium of knowledge bearing on its subject, but the form in which this is couched makes little appeal in these days. The book is intended, we presume, for the student of pure anatomy, yet, even so, we should like him to feel that anatomical knowledge is garnered for the purpose of its subsequent practical application in practice, whereas there is a regrettable want in the book of diagrams covering the points in which anatomy and clinical practice meet. There are no illustrations, for instance, of the segmental areas of the cutaneous nerve-supply.

#### JOURNALS.

*La Clinique Ophtalmologique*, November and December, 1918, and January, 1919.—The original articles in this journal include a description of Smith's intracapsular operation for cataract extraction illustrated by some excellent plates (A. S. and L. D. Green of San Francisco), articles by two of the editors, Jacqs and Darier, on the treatment of detached retina by puncture and subconjunctival injection, an article by Varrey-Westphal describing a new apparatus for the detection of partial colour-blindness, and others, besides the usual reviews of articles from other journals, French, German, Italian, Spanish, American, and a few English.

*Fourth Annual Report of the Ophthalmic Hospitals and on Ophthalmic Progress in Egypt during the Years 1915-1916.* By A. F. MACCALLAN, Director of Ophthalmic Hospitals. 1919. Cairo: Ophthalmological Society of Egypt. Bulletin of 1918.—From these reports we learn that the number of permanent ophthalmic hospitals built in Egypt during the ten years 1907 to 1917 was 13, and that there were in addition four travelling hospitals. The bulk of their work is concerned with trachoma and its sequelæ, the extent of this scourge being indicated by the fact that the proportion of the infected pupils in the primary provincial schools varied from 61 to 100 per cent. On the other hand, the danger of infection has probably been exaggerated, for Lieutenant-Colonel J. W. Barrett stated in the discussion on Dr. MacCallan's report that from February to November, 1915, when he was consulting oculist to the Forces in Egypt, he saw only 17 cases of trachoma amongst all the troops that came under his notice, and most of them were contracted in Australia. The number of operations performed for the relief of trichiasis and entropion in one year was upwards of 26,000. Next to trachoma, the chief cause of ophthalmic disease is the gonococcus, and Dr. MacCallan has for some years been noting the relation between the activity of this organism and the rise of the temperature curve, which appears to precede it at an interval of one or two months. The commonest causes of blindness, apart from conjunctival infection, are cataract and glaucoma, the percentage of blindness due to the latter disease being as high as 13.9. The glaucoma is nearly all of the chronic form and the usual

operation for it undertaken is trephining with iridectomy. Of the other papers contained in the Bulletin we may remark that in many of them the English sadly needs revision. There is one coloured plate of a case of coloboma of the choroid.

*The Optician and Scientific Instrument Maker.*—This weekly publication is frankly a trade journal, but contains articles of educative value to the optician dealing with the theory and practice of his calling. It also contains many articles dealing with the methods of sight-testing, and there is much controversial matter in which the claims of the sight-testing optician are championed. Into this controversy we do not propose to enter beyond pointing out that the refraction of children at any rate cannot be reliably estimated without the use of a mydriatic. We therefore regard the directions for correcting astigmatism and other refractive errors in children contained in the number for April 25th as a good deal worse than useless.

## New Inventions.

### A HUMERUS EXTENSION SPLINT.

THE difficulty in obtaining satisfactory extension in fracture of the humerus is well known to those who have had any large number to deal with. If the fracture is without loss of substance and without displacement it is found advisable to apply some form of extension if a perfect result is to be obtained; should there be displacement the need for extension becomes imperative; if there is displacement and loss of substance in addition—as so often happens in gunshot injuries—extension is necessary during the cleaning of the wound, even if foreshortening has to be resorted to later in order to get union. I have had the splint made which is here illustrated. The principle is found in the lever, which is used with a corkscrew to pull corks. By means of a double toggle in addition to the attachment at the fulcrum, the end of the lever, which is attached to the lower end of the fractured humerus, pulls in a straight line instead of through the arc of a circle as would happen if this double toggle were not put in. The

apparatus is attached to a Robert Jones splint. The extension apparatus is indicated by the letters. A B is an aluminium plate fixed to the under portion of the forearm section of the Jones splint, H K represents a lever attached to this plate at the fulcrum C D, the double toggle being shown as B F E. The extension is fixed to the lower part of the arm by glued stockette and the pull takes place from the lower end of it by means of tape attached to the lever at K, the direction of the pull being L K in the exact line of the intact humerus. Extension is obtained by an elastic upward pull at H by means of rubber tubing over a vulcanite pad moulded to the lower end of the forearm or it can be attached to the sides of the Jones splint. In the sketch the extension is shown to extend far up the arm, whereas it is fixed to the lower end of the arm only, and the hand is shown in a position midway between pronation and supination, but in actual practice the hand is put up in full supination; these explanations are necessary as the drawing is done so as to be as clear diagrammatically as possible.

The splint attachment can be obtained from Messrs. Allen and Hanburys, 48, Wigmore-street, London, W.

Whitby.

# THE LANCET.

LONDON: SATURDAY, JULY 5, 1919.

## The Passing of the Local Government Board.

It is with genuine feelings of regret that the older generation of medicine must witness the passing away of the Medical Department of the Local Government Board; for, owing to the fact that the Board ceased to exist on June 30th last, its powers and activities have been transferred to the new Ministry of Health. The annual reports of the medical officers of the Board embody the history of medicine in its practical and scientific aspects as applied to public health and the prevention of disease in England and Wales, and record a progress which is admitted to stand unique among the nations. Progress in public health knowledge has been largely due to the pioneer work of the Medical Department of the Board, and those who can look back on the history of sanitation through any considerable period of years will see those decades distinguished by a gradual increase in sanitary efficiency, originated or promoted by the medical servants of the Board.

Forty-eight years ago, when the Local Government Board was constituted by Act of Parliament, the knowledge of preventive medicine and public health administration was relatively small, and each advance had to be by way of experiment. It was the intention of the first medical officer of the Board, Sir JOHN SIMON, to make the Department a Ministry of Health, but, by an unfortunate decision of the President, measures for the improvement of the public health were made subordinate to the administration of the laws for the relief of the poor. SIMON was further hindered in his efforts by another decision of the President which prevented the medical officer from taking initiative action without having first received the sanction of the lay secretariat, who at that time neither understood nor appreciated the need for sanitary reform. Prior to the constitution of the Local Government Board public health legislation had been scanty and imperfect, and one of the first duties of the Department was, with the advice and assistance of the medical officer and his staff, to draw up a sanitary code for the country. But before this could be done the necessary machinery had to be provided, and for this purpose the Public Health Act of 1872 was passed, which divided the whole of England and Wales into sanitary districts, and made the appointment of medical officers of health and inspectors of nuisances compulsory in every district. This was followed by the Act of 1875, which codified and extended all the previous public health legislation. These two Acts were the foundation of real sanitary progress throughout England and Wales. At the time when the Board was created Great Britain was being ravaged by a

virulent epidemic of small-pox, accompanied by great loss of life. This necessitated reform of the existing arrangements for vaccination, which was accomplished by the passing of a series of Vaccination Acts and by the inauguration of a system of inspection by the Board's medical inspectors with the view of maintaining a high standard of vaccination throughout the country. These measures did much to diminish the prevalence of small-pox, and the subsequent inquiries made by the Medical Department, which led to the removal of small-pox hospitals from London and other populous centres, had great influence in arresting the spread of the disease. We may also refer to the great campaign instituted by Sir JOHN SIMON for the abolition of filth nuisances, which were then of common occurrence, a piece of strenuous work which was instrumental in reducing the incidence and mortality resulting from enteric fever and other intestinal diseases, while it added much to the comfort and decency of life among the working classes. It had been his intention to carry out a complete sanitary survey of the country and to place the results on permanent record, but unfortunately he was only allowed to do this in piecemeal fashion. Nevertheless, the inspections made by the Board's medical inspectors were productive of great improvement in the sanitary circumstances and administration of the districts visited by them. These visits were generally welcomed by the local authorities and their officers, who were anxious to discuss local sanitary problems and obtain the advice and assistance of the Board's expert staff. But, the number of medical inspectors was totally inadequate to carry out the policy for which Sir JOHN SIMON and his successors, notably Sir GEORGE BUCHANAN, Sir RICHARD THORNE, and Sir WILLIAM POWER, were responsible. Despite repeated applications for increase of staff, this inadequacy was allowed to continue and may be said to have never been removed. In view of these various circumstances it is the more remarkable that the sanitary progress of England should have been so rapid, but towards the close of the last century the Medical Department of the Board made one of its greatest moves forward. The first essential of a scheme for the administrative control of infectious diseases is that accurate information respecting the number and nature of such cases should be supplied to the medical officer of health of the district. This involved a system of notification with all the trespass upon privacy involved therein. To meet the strong prejudices in certain quarters the Notification Act of 1889 was made adoptive, and ten years later, when the value of notification had been universally acknowledged, the measure was made compulsory throughout England and Wales by the passing of the Infectious Diseases (Notification) Extension Act, 1899. It became one of the chief duties of the Board's medical inspectors to make inquiry into the circumstances associated with outbreaks of infectious diseases, and the long series of reports on the subject forms the basis of much of our modern knowledge of the epidemiology of the indigenous infectious diseases. The Medical Department of the Board was also largely responsible for the reform in connexion with port sanitary administration which led to the abolition of the obsolete quarantine regulations and their replacement by a system of medical inspection of shipping. This system has proved an efficient safeguard against

the introduction of diseases from abroad, and has been of great value to the maritime trade of the country. To Sir RICHARD THORNE belongs the credit of having demonstrated to the representatives of other nations at various international sanitary conferences the beneficial results of this system, and the present international sanitary agreements are largely based upon the English model. To Sir ARTHUR NEWSHOLME the country largely owes its increased sense of responsibility for its childhood, while under his dispensation the prevention of tuberculosis received special attention.

It is only by the recollection of these different landmarks, and by comparison of present conditions with those existing at various points in our sanitary history, that the nature, quality, and extent of the work of the Medical Department of the Local Government Board can be adequately appreciated. It has been carried out, often in circumstances of great difficulty, and its full measure of success is even now scarcely recognised by the public. But it has proved of incalculable value to the country.

### Peace and Famine.

POST-WAR conditions are in some cases even more terrible than those of war itself. Thus Lord CURZON—and General SMUTS adds: "We witness the collapse of the whole political and economic fabric of Central and Eastern Europe. Unemployment, starvation, anarchy, war, disease, and despair stalk through the land." While our public men have waited until the signature of the Peace Treaty to make these terrible facts generally known, they have long been realised by the initiated. The danger of epidemic disease has been so real to the inhabitants of the smaller European States that certain of them, though still in a state of war, sent representatives to arrange common measures of hygienic defence at a meeting held under the presidency of Dr. FERRIERE in Vienna. A sample or two of the findings of this International Red Cross Commission will suffice. In the Budapest Maternity Hospital, where 16,000 confinements take place annually, there were no sheets,<sup>1</sup> while the mattresses on which patients lay were filthy for the lack of means either to wash or to disinfect them. Dr. F. BLANCHOD, engaged in fighting typhus in Eastern Europe,<sup>2</sup> wrote of the entire absence of soap, linen, and medicaments, the resistance of the whole population being at the same time dangerously lowered as a result of famine and fatigue. Mr. R. KATZ, of Prague, who has recently been travelling with the Hoover Food Mission, recounts a terrible story of famine in the Erzgebirge<sup>3</sup>—the mountainous district between Saxony and Czecho-Slovakia. He computes that in these rural communities 90 per cent. of the children are rachitic, while hunger-œdema is so common as to be the rule.

If further proof were necessary of the physical effects of starvation on the population of Central Europe a summary is now available of RUMPEL's address on the effect of the war on nutrition, delivered at the Hamburg Medical Society at the beginning of April. Loss of weight to the extent of 20 or more per cent. he regarded as normal. Although certain cases of gout and fatty heart might have gained some advantage, yet in many

otherwise healthy people a symptom-complex developed, shown subjectively by palpitation and precordial pain increasing to attacks of pseudo-angina, objectively by diminution of the cardiac dullness, mobility of the heart on change of position, reduction of blood pressure, enteroptosis, wandering kidneys, dropping of the stomach, tendency to hernia with incarceration. Among the children, in whom during the first war-year little harm was noticeable, general weakness was now the rule, and a limitation of the stature proper to their age. To the famine known as "hunger-œdema," first described in 1917 by himself and later by VON JAKSCH, 22,000 cases had fallen victim in German Bohemia alone, with a mortality of 4 per cent. In Vienna a condition resembling osteomalacia had arisen. Tuberculosis had increased both in severity and in contagiousness. As regards illnesses in general, the length of convalescence was increased, hypersensitiveness towards remedies frequently showed itself, the blood changes included an increase in lymphocytes, with many cases of severe pernicious anæmia. Common also were gastric ulcer, the gastro-cardiac symptom-complex of ROEMHELD, polyuria, enuresis, and rapid surrender to fatigue. Apart from the terrible mass of suffering involved, these observations are of great intrinsic interest.

For the relief of this general distress our Treasury has agreed to add an equal amount to funds raised by voluntary organisations. To assist them in spending wisely the important Memorandum which we print on p. 28 has been drawn up by the Committee on Accessory Food Factors appointed jointly by the Medical Research Committee and the Lister Institute. The notes have been compiled with special reference to the famine districts of Eastern Europe, and the advice set forth is based upon the present state of our knowledge of the distribution of accessory food factors in natural foodstuffs and of the rôle played by them in preventing disease and in promoting health and growth. The antineuritic or antiberi-beri factor (water-soluble B), the fat-soluble A or antirachitic factor, and the antiscorbutic factor are described, and the foodstuffs in which respectively they do or do not occur are given in a table, which provides a convenient form for reference. This table is more comprehensive than any yet published, and indicates some interesting dietetic differentiations. Over 60 foodstuffs are thus catalogued. Chemists have not been able to throw much light on the composition and character of these accessory factors, which have, so far, not been isolated in their pristine state, and up to the time of the issue of this report their presence could only be determined by experiments with animals. So far as is known, the accessory food factors cannot be produced by the animal organism, and all animals are dependent for their supply directly or indirectly upon the plant kingdom. On the plant, therefore, rests the responsibility of averting the deficiency diseases. In time of peace the variety of food consumed by European nations protects them from risk of any shortage in these essential substances. Under present conditions, however, in addition to a general shortage of food, there is also a great restriction in variety. For the sake of the populations of Central and Eastern Europe there is abundant reason for spreading quickly a knowledge of the principles set forth in this report to guide the new spirit of generosity and humanity, born in the hearts of the peoples in this great hour of common suffering and sorrow.

## Seventy Years Young.

It is only 15 years ago that Sir WILLIAM OSLER was appointed Regius Professor of Medicine at Oxford. If his friends on both sides of the Atlantic—and no man has more, or more attached friends, most of whom feel that he is their own private crony—had not united at this moment to give him certain anniversary volumes as an expression of their affection, and by so doing revealed his birthday, no one would have credited him with three score years and ten. True he has long been before the medical public and is steeped in the wisdom of the ages; more than 20 years ago a distinguished foreigner, meeting a Johns Hopkins physician, inquired, "And how is your Osler? He must be centuries old." But he is always sympathetically of the same age as the person with whom he is talking; indeed, he often remarks when anyone's age is discussed, "Oh, he is our age." Many a true word is spoken in jest, and as a practical joker of no mean ability the Regius Professor is well able to hold his own with even the youngest of us—but that is another story.

If it is a great power, and our American and Canadian cousins certainly possess it, to get at once on good terms with strangers, it is surely a much finer talent to keep up these friendships in the way that the list of contributors to his anniversary volumes proves Sir WILLIAM OSLER can do. It is a long generation since Sir WILLIAM OSLER left Canada for the United States, but he is always acclaimed as the greatest Canadian physician. It was said on his departure from Johns Hopkins that his American colleagues deplored the loss of the man even more than that of the physician, and that this was a true saying is shown in this country by the way he has brought men together in London and Oxford, which has now become the Mecca of the United States and Canada, both socially and medically. He was obviously the proper chairman, not only for the newly instituted Fellowship of Medicine, which will welcome to London and this country generally visitors from the Dominions, America, and our Allies, but also for an efficient post-graduate scheme in London which is to cater for their professional needs. The Association of Physicians of Great Britain and Ireland was due to his inspiration, and the *Quarterly Journal of Medicine* has been brought out under his guidance since its birth in 1907. As President of the classical Association he has, like his brother Regius professor at the University of Cambridge, maintained the proper conception of the scholar-physician, equally versed in the experiences of the past, the potentialities of advancing research, and the practical steps of progress. For Sir WILLIAM OSLER has just been appointed a member of the Standing Committee to inquire into the financial needs of his University, and to advise the Government as to the application of any grants that may be made by Parliament towards meeting them. University education in the United Kingdom will thus have the advantage of his conciliatory common sense.

But in spite of all these multifarious activities no one can think of the man without recalling his love for books and their authors. As President of the Bibliographical Society, as an active curator of Bodley's library, and as a judicious collector of incunabula and other considered treasures, he has enough work to fill up the spare time of most young men. Of his favourite authors, Sir THOMAS

BROWNE, MONTAIGNE, OLIVER WENDELL HOLMES, and the EGERTON YORRICK DAVISES, father, son, and grandson (a family whom it is hardly an exaggeration to say he has rescued from oblivion) he probably most closely resembles the Knight of Norwich. There are few if any medical men who can give such charming addresses, full of kindly advice and graceful humour. To read his "Æquanimity" is a never failing remedy for bad temper. Of his infinite variety there is much more to say, but this we hope to be here to do on the 100th birthday which is his by hereditary right; and in the meanwhile we may recall OLIVER WENDELL HOLMES'S prophetic dictum: "To be seventy years young is sometimes far more cheerful and hopeful than to be forty years old."

## Annotations.

"Ne quid nims."

### DISABLEMENT AND ITS RELIEF.

THE evidence of Sir L. Worthington Evans, Minister of Pensions, given before the Select Committee of the House of Commons dealing with the administration of sailors' and soldiers' pensions, foreshadows timely changes in the method of dealing with disabled men. The number of pensionable men is now 720,000, nearly half of whom, it is estimated, require industrial training; only 11,000 of these men are yet undergoing training, while another 37,000 are desirous of training. The Minister referred to the transfer of the work of training disabled men to the Ministry of Labour, and indicated that the part of the work retained by the Ministry of Pensions is the training and treatment of the men so long as it is necessary for them to remain under medical care. Not only the men now being discharged from hospital will be admitted to the six or eight new residential convalescent centres soon to be established, but also the men discharged during the war who have been able to follow some employment (mostly unskilled) but still require medical treatment to make them efficient citizens. The Minister thought that these centres might usefully provide for the tuberculous "of the non-infectious type" and the relatively small number of men with extreme facial disfigurement for whom surgery could do nothing. The most economical unit for administrative purposes in the official view is 500. The first centre to be set going will be the converted filling factory at Hayes (Middlesex), where there are a number of isolated buildings convertible into dwellings and workshops served by a main building suitable for administrative purposes. As the grounds are nearly 200 acres in extent a course of agricultural training will be available. Men passed on to the industrial classes of the Ministry of Labour who break down during training will be returned to the convalescent centre. Such a centre might eventually be used as a permanent village centre occupied by the men and their families, especially tuberculous men. One cause of delay in pensions work—excessive centralisation—is to be dealt with, as already announced, by a welcome process of devolution, resulting in the establishment of 13 regions—two in Ireland, one in Scotland, one in Wales, and nine in England—each of which will be in the charge of a director who will have full powers in administrative matters. The anomalous and difficult position of the

medical referee is to be remedied by instituting Regional Appeal Boards staffed by consultants properly selected. In future the neurasthenic man, for example, will be actually seen by neurological experts, and no awards will be altered on inexpert hearsay evidence. The man dissatisfied with his award will still be able to go to his Local War Pensions Committee, who will be entitled to have the case reviewed by the Regional Appeal Board; their decision must, from the nature of the facts, obviously be final for a period. If the man's condition becomes altered he can go to the local medical referee, who will have the findings of the Regional Appeal Board before him and will be able to certify to what extent the man's present condition differs from the condition found by the board; the Local War Pensions Committee will be able to finance the man to the extent of this difference.

#### MONOPHAGISM, PELLAGRA, AND SCURVY.

THE theory which connects the ætiology of pellagra with maize, originated by Lombroso, has for the last ten years become the subject of renewed discussion. While on the one hand the geographical distribution of this disease is in close relationship with maize cultivation, laboratory experiments on the other hand have furnished no positive results in establishing this association. Professor G. Volpino,<sup>1</sup> of Bergamo, has recently investigated the subject from the point of view of anaphylaxis in pellagrous patients inoculated with extract of maize, and has shown that the injection of 1 to 2 c.cm. of watery extract of spoilt maize produces in them a distinct reaction affecting the nervous system, the skin, and intestinal functions. Sound maize had not the same effect. These phenomena, clearly anaphylactic, are caused by a super-saturation of the organism of pellagrous patients already rich in maidic substances, by a new maidic substance introduced experimentally. Other experiments in guinea-pigs confirmed this. These animals, after an exclusive diet of maize for 20 to 30 days, were inoculated with 0.5-1 c.cm. of the serum of pellagrous patients and died within 1-3 days, while control animals inoculated with serum from healthy individuals survived, as was the case also with other guinea-pigs fed on ordinary diet even if inoculated with double quantities of pellagrous serum. An exclusive diet (monophagism) is not of itself invariably harmful, especially when it forms the traditional food of the species; sometimes, however, it is not tolerated and causes pathological phenomena, as in beri-beri (Professor Volpino adds) and gout. The reasons why guinea-pigs fed exclusively on maize die are complex; the want of autineuritic and antiscorbutic vitamins is probably less important than the deficiency of grass, which is the traditional food of the species. As a result of this, the fact comes into play that the molecular grouping of the proteins of cereals are not analogous to those of herbaceous proteins, and the amino-acid content also is different. Moreover, it is probable that every kind of unsuitable diet, if persisted in, favours the entry into the circulation of a definite quantity of protein not completely split up into amino-acids, which causes, on the one hand, alimentary anaphylaxis, and on the other, the appearance in the blood of

ferments destroying the proteins themselves. In monophagism, therefore, there has to be taken into consideration not only the absence of certain groups, but also the presence in excess of other groups which are toxo-sensitising. Pellagra cannot be caused by deficiency of proteins in a diet of maize, for the amount of these is enough to satisfy the requirements of human food. It is always a disease of poverty, but the specific feature is to be found in the toxic or toxo-sensitising action of its over-abundant constituents. In the same way Professor Volpino considers that in scurvy there is a process of sensitising of the organism by a diet which is too exclusive, being deficient in certain constituents and disproportionately excessive in others. The same is true also of sprue and beri-beri. Professor Volpino, in view of the toxo-sensitising factor in pellagra, is led to consider the possibility of artificially increasing the resistance of animals to an exclusive diet. His researches have shown how this can be done within certain limits and the possibility of the extension of the method to human beings. Dr. Volpino's views, which are of a highly speculative nature, will find a suitable test in their application to the prophylaxis of relapses in pellagra.

#### HEALTH WORK FOR THE WHITLEY COUNCILS.

ABOUT a year ago the Whitley Councils of the Potteries and Printers set up a joint health committee which sanctioned an experimental scheme for regular medical observation and research in industry. The experiment, described by Mr. E. Halford Ross in a lecture delivered on Tuesday last before the Industrial Reconstruction Council, was made in two large printing works, where the employees were informed by both their employer and the secretary of the trade-unions that a doctor would attend periodically to advise the workers on health matters. As a result many came forward and asked advice. Observations were made while work was in progress and much was done to show employees how they might work under better conditions. In addition, numerous cases of disability were discovered and remedied and the experiment was considered to have been most successful. Certain researches were done concerning fatigue, hours of work, the provision of seats, and the advantages of welfare work generally. It was discovered that the health committee of each industry is the best means of carrying out this work. Each industry differs; each has its own requirements. It is, therefore, much better for each industry to undertake its own welfare matters than to leave it entirely to any Government department. This experiment suggests that further valuable research in industrial medicine might be carried out on a larger scale under similar conditions. Sufficient work has already been done in London during the last two and a half years to indicate some of the lines along which research should be pursued. Catarrh, bronchitis, and chronic cough are the most common obvious ailments which affect the workers, and it is very rare to find a large office without somebody in it suffering from a "cold." It is quite certain that a considerable sum of money is lost in London every week owing to the reduction of output caused by these complaints, in addition to the wages paid during sickness. It might quite possibly be demonstrable by experiment that economy would

<sup>1</sup> *Annali d'Igiene*, May-September, 1918. Rome, Via Palermo, 58.

be effected if workers suffering in the early stages of catarrh were persuaded to stay at home until they recovered. Anæmia is also of frequent occurrence among the young women and girl workers, and handicaps their work greatly. Out of several hundred employees examined in three large clothing factories 63 per cent. of the girls were found suffering from anæmia. This common disease can be easily prevented if taken at once when it appears. If left until well advanced each case may require months of treatment. Its prevention is a matter of education, and a little medical advice to parents in childhood will stop much of this disabling affection. Here is a matter which an industrial medical service could take up at once, and in which, working in conjunction with the School Medical Service, it would achieve wonders in a very short space of time. Anæmia has a most distracting effect on work, and may last for years, producing far-reaching results in motherhood. Again, from work that has been carried out in connexion with munition works during the war it appears probable that improper feeding has been a considerable factor in the production of fatigue, and that the short, hurried, and scrambled mid-day meal, accompanied by the discomfort of waiting in queues and the curtailment of rest, has resulted in a diminution of output. These questions are for scientific study rather than for political speculation, and under the ægis of the Whitley Councils medical men might well find an opportunity for impartial observation in a sympathetic environment.

#### MENINGITIS IN ANTHRAX.

At a meeting of the Société Médicale des Hôpitaux de Paris MM. Delater and Calmels reported a case of a rare complication of anthrax, namely meningitis. The patient, an American soldier, on June 14th noticed a pimple on the left cheek, which was slightly swollen. On the following day he was sent to hospital because he was feverish. On the way he vomited three times and momentarily lost consciousness. When admitted he was seriously ill. He was pale, covered with perspiration, and stuporous. The rectal temperature was 101.8° F. and the pulse 90. In the left parotid region was a "button" about 1 cm. in diameter, flat, greyish-white in the centre, surrounded by a rosy zone. The whole parotid region was œdematous, and the condition extended to the neck. There were no enlarged glands. When put to bed he at once assumed a curled-up attitude. Kernig's sign was positive and the neck was a little stiff. There were conjugate deviation of the head and eyes to the right, lateral nystagmus, and fibrillary contractions of the eyelids and lips. There was no meningeal streak. For two hours the patient remained in this state. Then general convulsions suddenly appeared and recurred every five minutes. In the intervals the patient was excited, turned in the bed, and tried to raise himself. The attacks of convulsions merged into one another, and death took place four hours after admission, just as lumbar puncture was about to be performed. It was performed immediately after death. The liquid, removed by aspiration, was rosy and turbid. To avoid error puncture was performed in several places, always with the same result. This rapid succession of meningeal phenomena during the time that the patient was in hospital rendered exact diagnosis very difficult. There was evidently a very acute infection or

intoxication, and without doubt a close relation between the meningeal condition and the parotid lesion. The necropsy showed soft œdema of the parotid and cervical region extending beneath the sterno-cleido-mastoid muscle. The internal jugular vein was thrombosed. The parotid gland was slightly congested. The meninges and cerebral convolutions were covered by a network of dilated veins filled with very black blood. There were no meningeal adhesions. All the thoracic and abdominal organs were normal. The hypothesis of anthrax had not been definitely entertained because the pustule had not had time to develop. Those who saw the patient thought of a boil complicated by jugular phlebitis, with œdema of the neighbouring parts, but after the bacteriological examination they recognised that the soft and extensive œdema was best explained by the diagnosis of anthrax. This was made certain by microscopic examination of the cerebro-spinal fluid, which showed numerous, much-altered polynuclears and many Gram-positive filaments, containing spores, and free spores. The bacteria had the squat appearance with square ends characteristic of anthrax. Cultures were typical, and a guinea-pig inoculated therewith died in 40 hours with the usual symptoms and lesions.

#### STATE-APPLIED PHYSIOLOGY.

Mr. G. H. Roberts, the Food Controller, recently told the executive officers of food control committees that the total cost of controlling the food supply of the country worked out at about 10d. a year per head of the population. The Consumers' Council has since decided that this tenpenny rate is well spent, and has formally recommended the continuance of a Ministry of Food. At the Carlisle Coöperative Congress last month two resolutions were carried, the combined effect of which would be the continuance of many, if not all, of the measures taken during the war for regulating the distribution of food. A member of this congress declared that food control began two years too late and is ceasing two years too soon, and this was evidently a view which commended itself to the majority of his hearers. However insistently a large number of persons have demanded the removal of food control at the earliest possible moment, its abolition is being regarded by at least as many with apprehension. Their fears may be exaggerated, the iniquities of the food profiteer may not be as black as they have been painted. But the question does arise whether the law of supply and demand can be trusted to bring down prices rapidly and to obtain a just division of available supplies, or whether the limited amount of food likely to be put on the market in the near future will enable unscrupulous speculators to obtain monopolies which more abundant supplies would render difficult or impossible. The average citizen who dislikes the food profiteer cordially at the same time has a suspicion that the law of supply and demand must ultimately prevail against him. Nevertheless, he is anxious lest meanwhile the desire of him who has the longest purse to live luxuriously will operate to the disadvantage of those whose means are more limited.

The stringent application of the coupon system, when our supplies and our prospects of future supplies were at their worst, admittedly effected a necessary economy. It promoted and maintained a contented feeling among the population in general. Both good things. But it did more than this. It

enabled the whole nutritive problem of the country to be studied as never before by the best scientific brains, and this surely is the most cogent argument of all for the existence and maintenance of food control. It will enable the nation to retain the services of their scientific food advisers. How necessary this is the latest report of the Food (War) Committee of the Royal Society, to which we have already alluded, is sufficient evidence. This concludes with the pregnant words: "The above report shows how very inadequate is our present knowledge of the science of nutrition, and demonstrates the necessity of renewed investigations on almost every point discussed in it." Sir Auckland Geddes recently remarked that the universities, through the professors of the various faculties, had contributed more fully to victory than any other organised section of the community, and he begged men of science in future not to remain dumb at critical periods, but to come forward to help the country. It would be hard to devise a more efficient medium for the vocal help sought than such a Royal Society's committee. Professor E. H. Starling's recent Oliver Sharpey Lectures on the Feeding of Nations: a Study in Applied Physiology, were a luminous exposition of the results which may be thus obtained. Even the most cursory study of these lectures should convince our legislators that the scientific method will and must pay. Let them only compare the debit and credit sides of the food balance-sheet. The continuation in being of an expert advisory committee at the Food Ministry will serve to build up a body of sound data from which the needs of the community may be accurately computed. Nor is this the only department outside the Ministry of Health that needs such expert advice. The fixing of a minimum wage is ardently desired. On what basis should this be founded, the cost of living, the æsthetic conditions of labour, the amenities of life, or the actual energy expended? Here is another problem which applied physiology should help to solve.

#### DEPOPULATION.

AN aspect of the reconstruction problem which is gravely exercising statesmen is that of the maintenance of a sufficient population to carry out any projects of reform which may be deemed necessary. Perhaps, in course of time, the National Birth-rate Commission may have some helpful recommendations to offer, and meanwhile those who wish to learn how the matter presents itself to a Frenchman may care to read a work entitled "La Natalité," written by Professor Gaston Rageot,<sup>1</sup> in which he discusses the economic and psychologic laws which have determined modern views as to the place of the child in the social scheme. It is his desire, he says, "to dissipate some of the illusions which envelope the problem of natality," the principal being the belief that it is a simple one which may be solved by particular measures such as the award of premiums or the grant of allowances. His statement of the position is philosophical, and he displays none of the special weakness to which debaters of this subject are prone—an inability to realise that the demolition of an opponent's argument by means of a triumphant *reductio ad absurdum* does not, of itself, show that one's own case is any better. A low birth-rate is, he finds, associated historically with extremes of civilisation which are themselves incompatible with the existence of the family. It is natural, he

says, for human parents not to concern themselves about their children. "Ce n'est pas la nature qui protège l'enfant, mais la société." And society is for each of us only an abstraction which becomes concrete and living when it stands for "la patrie en danger." To the French mode of devolution of property, which has been held to discourage the production of large families, he attaches little importance, if only for the reason that in England freedom of testamentary capacity has not prevented a fall in the birth-rate; its effects, too, have varied—it stimulated natality under the Revolution and depresses it to-day. Summing up the various factors which he has dealt with at length he concludes that "la fausse démocratie produit le dépeuplement," but he is not without hope of better things.

#### TRAUMATIC ADDISON'S DISEASE.

THE subject of traumatic Addison's disease is discussed by Dürck,<sup>1</sup> who reports the following case. A hitherto healthy man, aged 48, was caught between a railway carriage and a revolving platform and had four ribs fractured. Apparent recovery took place, and he was able to resume his work in about six weeks, but a week later he had to give up owing to weakness in the arms and legs and palpitation. Bronzing of the skin of the face and hands gradually set in and the muscular weakness increased. Treatment consisted in the administration of suprarenal preparations, and death did not take place until about eight years after the accident. The autopsy showed considerable bronzing of the skin of the face, hands, forearms, and external genitals, and apparently complete absence of both suprarenals with a healed fracture of the sixth to the ninth ribs on the right side. On microscopical examination some necrotic fragments representing the remains of the medulla of the left suprarenal were found, while on the right side there was hardly any trace of the suprarenal, but remains of blood pigment indicated that a hæmorrhage had formerly taken place in this situation a long time previously. Tuberculosis could be excluded, and there was no evidence of syphilis.

#### A CHILD-BEARING STRIKE.

THE insertion at the front of the most recent number of the *Munich Medical Journal*, which has reached us, of a polemic against a threatened child-bearing strike in Bavaria is something of a portent. The author, Fritz Burgdörfer, a doctor of public economy holding office in Munich, begins by calling attention to the active propaganda at present being carried on in that city, directed towards a prevention of conception and an encouragement of intentional abortion, leading up to a demand for what amounts to a strike of child-bearers. This "communistic" programme, Dr. Burgdörfer tells us, assumes that the population of Germany is at present too large by 30 millions, and that since under present conditions the usual outlets in the form of exported goods or emigration are impracticable, the cry should be "No more children!" since even a wise peasant does not breed more cattle than he can feed. Largely attended public gatherings in Munich have, we learn, been instructed in the systematic use of conception-preventing apparatus, the instruments themselves being shown and their application described. Dr. Burgdörfer's reply to all this is

<sup>1</sup> Paris; Ernest Flammarion.

<sup>1</sup> Aertzl. Sachverständ.-Ztg., 1919, xxv., 73-81.

to quote at length Parts 1 and 2 of the 1919 Blue-book of the Bavarian Statistical Office giving the official figures for the changes in the population during the period of the war, which is over. The result is, he truly says, extremely sad. In place of the usual abundant excess of births over deaths the effect of the last five years upon the Bavarian population has been as if:

(1) One year and eight months long no marriages had taken place.

(2) Two years long no children had been conceived.

(3) Three years long double the usual number of human beings (excluding children under 5 years) had died.

The married couples in the country had not only substantially diminished in number but their average age had increased and their procreative ability was less. All in all, at the end of 1918 the baby budget showed a deficit of roughly 400,000. Applied to the pre-war German Empire as a whole, of which the Bavarian population formed one-tenth part, the profit and loss account might be so stated: 800,000 marriages not made, 4 million children unborn, 1.6 million military persons died, 700,000 civil persons died in consequence of the hunger blockade—as compared with normal times. These massive figures, Dr. Burgdörfer thinks, speak of a situation so serious that the communistic propaganda must be controverted at all costs. At the moment there are not too many children but too many adult men in Germany. A child-bearing strike would come too late and produce its maleficent results two decades hence, when they would be an anachronism. Any nation that practises a one-child system is going to its destruction. His motto is "Work, Peace, and Order," in the belief that "The greatest riches of any people consist in the people itself."

#### METROPOLITAN WATER-SUPPLY RESEARCHES.

THE thirteenth annual report on the results of the chemical and bacteriological examination of the London waters for the 12 months ended March 31st, 1919, was issued last week and presents some novel features, inasmuch as, arising out of the events of the war, certain important changes have been introduced in waterworks procedure. We gather from the observations of the Director of Water Examination to the Metropolitan Water Board, Sir Alexander Houston, that the new methods of water purification adopted will form the future policy of the Board. It is clear from the report that during the period of the war, and excepting temporary periods of unusual stress, the average quality of London's water-supply has been wonderfully well maintained, especially in view of the extraordinary difficulties, often of a cumulative sort, which the engineering department has had to face. Sir Alexander Houston admits, however, that it is disappointing to have to point out that for the current year the New River, East London (Lee), and Chelsea bacteriological results are the worst since the work was started under his control. The floods were responsible in the first two cases, and as regards Chelsea, the works "were asked to do too much in relation to the filtration area." The chlorination of the river waters has been continued, and this process, it is reported, succeeds considerably better than storage on the average, and is practically three times superior in its winter effects, when both the river water and the storage water give the least satis-

factory results. These statements are based on the results of bacteriological examination (the *B. coli* test). The saving of coal by the adoption of the chlorination method as compared with the storage method is a very remarkable factor in the case. Chlorination further has an important deterrent effect on the development of algæ or other vegetal growths, often a source of great inconvenience and trouble to water engineers. The Staines reservoirs were affected with these growths, which showed prominently in the photographs taken of the suspended matter, but they rapidly disappeared when chlorinated river water was once more used for supply purposes. Again and again these reservoirs were, during flood-time, heavily "seeded" with growths, yet when the floods subsided and chlorinated river water was again the source of supply the growths vanished relatively quickly. It would thus seem to be the case that when chlorinated river water is stored for only a short time there is no serious risk of growths, even if from time to time a reservoir water is used which contains growths in great abundance. These water researches have obviously involved much well-directed study and the progress reported is admirable.

#### THE DEATH OF LORD RAYLEIGH.

THE death is announced of Lord Rayleigh, in his 78th year. Thus has passed away one who, from the boyish days of his senior-wranglership, had devoted his life, with fruitful results, to the solution of problems of fundamental importance in physical science. Director of the Cavendish Laboratory at Cambridge, where he occupied the chair of experimental physics, he was led to study the physical properties of nitrogen from various sources, with the result that he found the nitrogen of the air slightly heavier than pure nitrogen obtained by chemical means. Could such a discovery be made more fitly than in the Cavendish Laboratory? The residue which the great Cavendish obtained in 1785 after oxidising the nitrogen of the air by "sparking" proved ultimately to be the factor which caused nitrogen in Rayleigh's experiment to be heavier. It was a heavier gas mixed with the nitrogen and subsequently was isolated in a pure state and called by Ramsay, from its inertness, argon. This led to the discovery of other gases in the atmosphere, and the methods employed brought helium to light. In many other directions Lord Rayleigh carried out investigations of both scientific and practical importance. His memoirs on sound, electricity, and optics formed a series of scientific contributions much valued by the Royal Society, of which he was President in 1905. He brought about, also, valuable reforms in the teaching of science and in educational methods generally. Physical science has lost one of its most distinguished exponents by the death of Lord Rayleigh; he is succeeded in his peerage by his son, Mr. R. J. Strutt, F.R.S., who is also a leading physicist.

#### INDEX TO "THE LANCET," VOL. I., 1919.

THE Index and Title-page to Vol. I., 1919, which was completed with the issue of June 28th, is published in this number of THE LANCET. We are glad to be able to restore this pre-war custom, now that it is justified by a more liberal supply of paper.

## ACCESSORY FACTORS IN FOOD.

THE Memorandum which follows has been drawn up by the Committee on Accessory Food Factors, appointed jointly by the Medical Research Committee and the Lister Institute, for the guidance of those engaged in administration of food relief to famine-stricken districts. It is signed by the chairman of the committee, Dr. F. Gowland Hopkins, F.R.S., and the secretary, Miss Harriette Chick, D.Sc.

*Introduction.*

Recent research has shown that the requirements of the human organism as regards diet cannot be met entirely by an adequate supply of protein, fat, carbohydrate, inorganic salts, and water. It has therefore modified the common belief of ten or more years ago, when the attention of physiologists was focussed upon the calorie or energy value of the diet. It is now established that, in addition to these necessary constituents, certain unidentified principles, known as accessory food factors or "vitamines," must also be present in order to maintain health and prevent the occurrence of "deficiency diseases." These substances have not so far been isolated, little is known of their chemical or physical properties, and at the present time their presence can only be detected by experiments with animals.

These accessory factors or vitamins are widely distributed among naturally occurring foodstuffs, and in time of peace, under normal conditions of food supply, the variety of food consumed by European nations protects them from risk of any deficiency in these essential substances. Under the conditions arising from the war a different state of things exists; in addition to a general shortage of food there is also a great restriction in the variety available, and danger from "deficiency diseases" is to be feared.

Of these diseases scurvy is the best known, and the belief that it is caused by some deficiency in the diet has long been strongly held. Recent research has added to the deficiency diseases beri-beri, rickets, and other less well-marked disorders of growth and departures from health.

The following notes have been compiled by the Committee on Accessory Food Factors in the hope that they may afford practical help to those occupied in the administration of food relief to the famine districts of Eastern Europe. The advice given is based upon the present state of our knowledge of the distribution of accessory food factors (vitamines) in natural foodstuffs and of the rôle played by them in preventing disease and in promoting health and growth.

*Accessory Food Factors.*

The accessory food factors at present recognised are three in number:—

(1) Antineuritic or antiberi-beri factor, identified with the "water-soluble B" growth factor of the American investigators.

(2) Fat-soluble A growth factor or antirachitic factor.

(3) Antiscorbutic factor.

As far as is known the accessory food factors cannot be produced by the animal organism, and all animals are dependent for their supply directly or indirectly upon the plant kingdom.

*Distribution and Properties of the Accessory Factors.*

1. *Antineuritic or antiberi-beri factor* ("water-soluble B" growth factor of the Americans).—This vitamine prevents the occurrence of beri-beri in man and analogous diseases in animals. It is also necessary to promote satisfactory growth in young animals. It is widespread, and is found to some extent in almost all natural foodstuffs. Its principal sources are the seeds of plants and the eggs of animals, where it is deposited, apparently, as a reserve for the nutrition of the young offspring. Highly cellular organs, such as the liver and the brain, contain considerable amounts of this vitamine; flesh contains comparatively little. Yeast cells are a rich source; so also are yeast extracts—e.g., "marmite." In the case of peas, beans, and other pulses, this vitamine is distributed throughout the seed, but with cereals it is concentrated in the germ (embryo) and in the peripheral layer of the seed which in milling is peeled off with the pericarp and forms the bran.

Beri-beri is occasioned by a diet composed too exclusively of cereals from which germ and bran have been removed by milling, as in the case of polished rice or white wheat flour. The disease is common where polished rice is the staple

article of diet to an almost entire exclusion of other food-stuffs. It is rare, though not unknown, where white wheat bread is eaten, because the consumption of this type of cereal food is usually accompanied by a sufficiency of other food-stuffs containing the essential principle. It is unknown where rye bread is the staple food, because in the milling of rye there is no separation of the germ.

2. *The fat-soluble A growth factor or antirachitic factor* necessary to promote growth and prevent rickets in young animals.—This vitamine appears to be necessary also to maintain health in adults, and it has been suggested that war oedema may be due to a lack of this factor in the diet. The main sources of this factor are two in number: (1) Certain fats of animal origin; (2) green leaves. The most notable deposits of this factor are in cream, butter, beef fat, fish oils (for example, cod-liver oil, whale oil), egg yolk. It is present in very small or negligible amount in lard (pig fat) and in vegetable oils, as, for example, linseed oil, olive oil, cotton-seed oil, coconut oil, palm oil; pea-nut or arachnis oil is reported to contain it in larger amount. It will be noticed that this factor is found chiefly in the more expensive fats.

While green-leaf vegetables contain the fat-soluble factor, root vegetables are deficient in it; war oedema has been frequently reported under circumstances in which root vegetables have formed a large proportion of the diet.

3. *Antiscorbutic factor*.—This vitamine is necessary in a diet for the prevention of scurvy, and is found in fresh vegetable tissues and (to a much less extent) in fresh animal tissues. Its richest sources are such vegetables as cabbages, swedes, turnips, lettuces, watercress, and such fruits as lemons, oranges, raspberries, tomatoes. Inferior in value are potatoes, carrots, French beans, scarlet runners, beetroots, mangolds, and also (contrary to popular belief) lime juice. Potatoes, although classed among the less valuable vegetables as regards antiscorbutic value, are probably responsible for the prevention of scurvy in northern countries during the winter owing to the large quantities which are regularly consumed.

Milk and meat possess a definite but low antiscorbutic value.

This vitamine suffers destruction when the fresh food-stuffs containing it are subjected to heat, drying, or other methods of preservation.

All dry foodstuffs are deficient in antiscorbutic properties; such are cereals, pulses, dried vegetables, and dried milk.

Tinned vegetables and tinned meat are also deficient in antiscorbutic principle. In case of tinned fruits the acidity of the fruit increases the stability of the vitamine, and prevents to some extent the destruction which would otherwise occur during the sterilisation by heat and the subsequent storage.

An appended table gives a summary of our knowledge as to the distribution of these three accessory factors among the commoner foodstuffs.

*Practical Application of the Foregoing Facts to the Prevention of Disease.*

1. *Prevention of beri-beri*.—It is unlikely that any danger of beri-beri will arise among the famine threatened districts of Eastern Europe as long as wholemeal flour from rye, wheat, barley, maize, or peas, beans, and lentils are provided. Mere shortage of food does not cause beri-beri, and poverty ensures that the whole grain is consumed for purposes of economy.

2. *Prevention and cure of rickets or growth failure in children or war oedema in adults*.—Evidence is accumulating that rickets is caused by a shortage not of fat as such, but of the "fat-soluble growth factor" which is contained in certain fats. Xerophthalmia, a severe disease of the external eye, leading, if untreated, to blindness, has also been attributed to lack of this factor. Infants and young children must therefore be supplied with the *right kind of fat*. To prevent rickets (1) full cream milk should be secured for artificially fed infants when possible; failing that, (2) full cream dried milk or (3) full cream unsweetened condensed milk. (2) is preferred to (3), and, in case of ignorant or careless mothers, even to (1), in order to prevent spread of infection and intestinal disorders. In all cases where (2) or (3) are used an extra antiscorbutic should be given (see below).

Sweetened condensed milk is undesirable for the reason that the degree of dilution required by the high sugar content renders the food, as prepared, deficient in the fat-soluble (antirachitic) factor as well as in fat and protein.

Milk and butter are the best sources of the antirachitic (or fat-soluble) factor for young and growing children;

Table showing the Distribution of the Three Accessory Factors in the Commoner Foodstuffs.

Classes of foodstuff.	Fat-soluble A or anti-rachitic factor.	Water-soluble B or anti-neuritic (anti-beriberi) factor.	Antiscorbutic factor.

\* Value in proportion to amount of animal fat contained.  
V. slight = Very slight.

margarines made from animal fats are also valuable; those made from vegetable oils are to be condemned. If there is a shortage of butter it should be reserved for children, but if totally lacking the deficiency can be replaced by cod-liver oil and other fish oils or by eggs. If all animal fats are unavailable pea-nut oil should be selected in preference to other vegetable oils for preparation of margarines, &c., and some effort should be made to utilise the fat-soluble vitamins contained in green leaves.

Green leaves are a cheap and readily available source of the fat-soluble vitamins, and adults can probably maintain good health when animal fats are substituted by vegetable fats if green-leaf vegetables are consumed in fair quantity. In case of this vitamin the loss involved in ordinary cooking is not serious. Unfortunately infants or very young children cannot take green vegetables in the ordinary way, but the juices expressed from cabbages and other green-leaf vegetables, raw or even after steaming (not immersing in boiling water) for a few minutes, might be given even to infants if all other sources of this most necessary vitamin have failed.

Purées, carefully prepared from cooked spinach or lettuce, can be tolerated in small quantities (one teaspoonful daily) by many young infants, and the amount taken can be increased regularly with age.

In cases where rickets or growth failure or xerophthalmia are already well established a daily dose of cod-liver oil is essential in addition to all other procedure.

Pregnant and nursing mothers should have as liberal a supply of the fat-soluble factor as is possible. Rickets is not confined to artificially-fed children. Breast-fed children depend for an adequate supply of fat-soluble vitamins on the milk, which in turn depends upon the diet of the mother.

3. *Prevention of scurvy: use of germinated seeds.*—If fresh vegetables or fruits are scarce or absent an antiscorbutic food can be prepared by moistening any available seeds (wheat, barley, rye, peas, beans, lentils) and allowing them to germinate. It is necessary, of course, that these should be in the natural whole condition, not milled or split. The seeds should be soaked in water for 24 hours, and kept moist with access of air for 1-3 days, by which time they will have sprouted. This sprouted material possesses an antiscorbutic value equal to that of many fresh vegetables, and should be cooked in the ordinary way for as short a time as possible.

In case of shortage it should be remembered that salads are of more value than cooked vegetables. The extent to which the antiscorbutic factor is destroyed during cooking depends chiefly upon the time employed. When supplies are limited vegetables should be cooked separately and for as short a time as possible; they should not be cooked for long periods with meat in soups or stews.

Preserved foods, with a few exceptions, may be regarded as devoid of the antiscorbutic principle. Lemon juice retains some value in this respect; canned tomatoes (and presumably other tinned acid fruits) have also antiscorbutic value. *Canned vegetables are useless for prevention of scurvy, as also are dried vegetables.*

Infantile scurvy must be considered separately, as many of the above foodstuffs are unsuited to infants or young children. To avert danger all artificially nourished infants should receive an extra antiscorbutic. Cow's milk, even when raw, is not rich in the antiscorbutic vitamin; when heated, dried, or preserved, the amount contained is still further reduced. The most suitable antiscorbutic material to use is fresh orange juice, 1-3 or 4 teaspoonfuls (5-15 c.cm.) daily, according to age. Raw swede (or, if unavailable, turnip) juice is a potent antiscorbutic, and an excellent substitute for orange juice; to obtain the juice the clean-cut surface is grated on an ordinary kitchen grater and the pulp obtained is squeezed in muslin. Tomato juice, even from canned tomatoes, and grape juice can also be used; the latter is, however, less potent than orange juice, and a larger dose should be given.

Pregnant and nursing mothers.—If babies are breast-fed it is important that the pregnant and nursing mother should receive an adequate supply of antiscorbutic food in her diet. The popular belief that green vegetables are harmful in such cases is often without foundation. Infantile scurvy is not unknown in breast-fed children.

It is evident that many of the above deficiency diseases are rife among the populations of Central and Eastern Europe. It is essential, therefore, that the principles set forth in the preceding paragraphs should be fully understood by all persons engaged in administering relief to these districts.

## AN INDUSTRIAL MEDICAL SERVICE.

### II.—HOW TO START AN INDUSTRIAL MEDICAL SERVICE.

SOCIAL organisation has always followed the lines of evolution, wherein the cell came first, then a group of cells, then a nervous system; similarly, in the social world first came the family, then the tribe, then the governed nation: New services should be allowed to evolve, and not be forced into existence on plans drawn up in some official headquarters.

The need for an industrial medical service has been dealt with in a previous article; the present intention is to show how it can be started. Its subsequent evolution may thereafter be safely left to the future. The first point to have in mind is that a medical service to be effective should acquire the momentum of popular interest, which can only be obtained through direct touch with the personality of those it serves. This is fundamental, and its absence in the past from public health medicine is some explanation of why the average citizen has taken so little interest in the health of the community of which he is a part, although he is only too ready to discuss personal medical topics. The next point is consideration of the duties to be undertaken. These concern industrial birth, life, and death. Industrial birth is the engagement of workers; and here medical services are of great value. A medical officer acquainted with industrial processes may reject a heart case, a myope, or an incipient hernia for some processes, but safely accept them for others; as he gains more experience he will choose persons for special work according to their capacity as measured by alertness, physique, acuity of hearing or of vision; in short, he will adjust round pegs into round holes, and so do much to avoid the great economic waste of labour turnover, the result of the present method of trial and error which leaves the worker to try place after place until a congenial one is found; by thus examining each newcomer personal contact is established which should never be lost. Industrial life is the period of employment; and here skilled medical services are of even more value; to determine the existence of fatigue, the optimum hours of labour, the presence of faulty ventilation or bad lighting; to supervise the hygiene of workplaces; to arrange for dental supervision; to deal with outbreaks of epidemic disease; to advise on the provision of a canteen and its food-supply, of cloakrooms, of washing facilities, and of suitable overall clothing; to watch lost time and sickness records; to supervise closely the health of those employed on dangerous processes; to organise first-aid treatment and establish contact with outside medical treatment; to advise on compensation cases. Here personal contact should be maintained and strengthened, and the medical officer become the friend and adviser of all. Industrial death is the cessation of employment; and here the medical officer should inquire closely into the causation of dismissal or leaving so that he may ascertain where his practice is at fault; such inquiry should be for him what a post-mortem is to the physician and surgeon.

Every industry will have its own special problems; but the above short summary of the work to be done suggests where it must start—viz., in industry by the retention of whole- or part-time medical services by employers of labour. The employer will gain in the quality and quantity of output far more than the salary he pays; the worker will benefit by improved health, happiness, and earning capacity. A few employers have already taken this step; and probably more would follow if they could obtain medical men adequately trained, but there are not many who on perusing the above rough list of duties would consider themselves trained to undertake them. Two things are now needed, an increased supply of trained men and an increased demand for their services. The increased supply could rapidly be met by post-graduate courses held at medical schools in industrial areas; Birmingham, Bristol, Cardiff, Glasgow, Manchester, and Sheffield suggest themselves. Practitioners in industrial areas all suffer from lack of knowledge of how their patients earn their livelihood, and would willingly attend such courses. One group of the profession should in this matter take the initiative, both in pressing the schools to start courses and in attending the courses; we refer to the certifying factory surgeons. They already possess a recognised association and

are in touch with the factories and workshops; but the duties entrusted to them, as they are aware, are wholly inadequate to the needs of industry.

The increased demand would follow almost automatically from the existence of the supply for each trained practitioner in his daily work would influence the men and their unions on the one side, and the employers and their councils on the other. Both sides would soon appreciate the value of a medical attendant with an intelligent understanding of industrial problems and ready to use his knowledge to their advantage.

Our appeal, then, is to the great provincial medical schools to start post-graduate courses in industrial medicine directed to meet the needs of the district, and so be of direct and immediate benefit to the industries among whom they exist, in the sure and certain hope that the industries in their turn will react and give greater financial support to the schools. The schools need financial support, and it is more likely to be forthcoming if the schools pay attention to the particular needs of industry and establish clearly the value industry will get in return.

## MEDICINE AND THE LAW.

### *Treatment by Correspondence.*

AN inquest was recently conducted at Kensington, by Mr. A. D. Cowburn, on the body of a woman, aged 46, who died from tuberculosis and heart disease in the absence of treatment by any qualified medical man. According to the report of the proceedings in the *Times* for June 6th, it appears that until April last she had been treated by a throat specialist in Brazil, where she was then resident, and had, on coming to England, applied, through her husband, to the Alabone Institute in Highbury Quadrant, filling up a "form," and being supplied with an apparatus for spraying the throat, and with medicine. On May 31st the husband, finding that her condition was becoming very grave, wrote to the institute demanding the personal services of "the doctor who had the case in hand." On the following day it became necessary to call in a local medical man, who pronounced death imminent, as indeed it proved to be. Evidence as to the pathological conditions found post mortem was given by Dr. B. H. Spilsbury, who is reported to have said that, had proper treatment been given, life would have been prolonged. The husband of the dead woman having declared that he was under the impression that the "doctor at the institute was a qualified man," the coroner stated that he intended to call the attention of the proper authorities to the matter. It appears certain that in this case the inadequacy, at least, of "treatment by correspondence" for one in so grave a state of health, was not appreciated by those on whom the responsibility for her welfare devolved; but the husband evidently believed that the treatment he procured his wife was legitimate, and conducted by a qualified medical man in a proper manner, though in absentia. Any action that may be taken by the authorities will probably be conditioned by the strength of the evidence available that the husband had grounds extended to him for this belief: but it may be that, even if such evidence be not forthcoming, there is yet sufficient basis for action by the Society of Apothecaries, which society, it will be remembered, has the right to sue for penalties against persons practising as apothecaries without its licence. The practice of an apothecary consists, it is usually held, in attending and advising persons requiring medical treatment, and in prescribing, compounding, and supplying medicine for their cure and relief. Bone-setters and others of that ilk do not therefore expose themselves to the liability of such action. But it is clear that, in the interests of others who may be misled from one reason or another, the activities of the Alabone Institute call for close attention.

### *The Dispensing of Prescriptions at Night.*

At a recent inquest at Deptford it was proved that an insured person who had received a prescription at eight in the evening could not obtain the medicine till the following day because the druggists available would not dispense after that hour. In the view of the medical man who gave the prescription, the life of the patient, who died, might have been saved if he could have obtained the prescription at once. He stated that similar cases were happening every

day. The coroner expressed the opinion that in urgent cases druggists should be compelled to dispense at any hour of the day and night, and that the matter should be brought to the attention of the Insurance Committee. This, he was informed, had already been done without result. It would certainly appear to be useless for medical practitioners to be compelled, by public opinion if not by law, to attend patients at all hours—often for illness which is not serious or urgent—when in cases of genuine urgency the effort of the medical man is frustrated by the closing of the druggist's shop. It is for the public to bring about the remedy in their own interests.

#### *The Proof of Paternity.*

In a recent trial before Mr. Justice Darling a man indicted under the Punishment of Incest Act, 1908, raised the defence that the girl with whom, according to the evidence, he had had sexual intercourse, was not in fact his daughter. She had been born two months after the prisoner married her mother, but he denied that he had had, or could have had, access to the mother at the time when the child must have been begotten. The law presumes a child born in wedlock to be the legitimate offspring of the marriage, and when the Punishment of Incest Act was framed, in order to prevent intercourse between persons closely related in blood, the position of those connected only by a legal presumption was possibly forgotten in the drafting. Mr. Justice Darling, while referring to authorities of great weight against the course which he took, relied upon the Poulett peerage case as enabling the presumption of legitimacy to be rebutted. He therefore left it to the jury to say whether the girl was the daughter of the prisoner by blood or not, and told them that it was their duty to acquit him if they were satisfied that she was not his daughter in the sense indicated. The prisoner was found not guilty and discharged. Defences of this kind will probably be heard of again at similar trials, and it is to be hoped that they may not lead to undeserved acquittals.

#### *Professional Secrecy in the Eye of the Law.*

An interesting statement was made by the presiding judge during the hearing at the last Worcester Assizes of a case of concealment of birth. One of the witnesses, a medical man, was called in when the girl was prostrate, and after she had placed the body of the baby under the mattress. He said he had to perform an operation to save her life. The judge said he saw that the doctor in his depositions had stated that though he knew the child had been born, he did not think it his duty to inform the police, as it would have been a gross breach of professional confidence. The judge said there was no professional confidence in criminal cases, and it was the doctor's duty to inform the police. He did not blame the doctor for his view, but he thought it should be known that his view was wrong, as was that of the Association which advised him. The judge added that if a patient cut another person's throat it would be the doctor's duty to inform the police. There was no difference between these cases. In the result the girl was found not guilty. The question thus raised is, of course, not new and its solution is not easy. It has been frequently discussed, and an able exposition of the whole subject was given by the late Dr. A. G. Bateman, the Secretary of the Medical Defence Union, in a paper which, with a report of an interesting debate, is to be found in the Transactions of the Medico-Legal Society for 1904-05. It would appear that the dictum of the learned judge presiding at the recent Worcester Assizes is in absolute accord with the strict letter of the law. It is equally clear that the judge did not consider that, in this case, there had been any but a technical breach committed by the doctor. His actions were fully in accord with the paramount professional opinion which finds it repugnant to assume the office of informer, when knowledge of the indictable offence is obtained in the exercise of professional capacity. This opinion is clearly set out in our columns this week by Sir John Tweedy, President of the Medical Defence Union. Nevertheless, it is well that the letter of the law should be known, and that the responsibility for non-compliance, under certain circumstances, should be realised. A medical man in the exercise of his professional vocation has special opportunities for becoming aware of the commission of offences against the law, and special confidence is reposed in him. The law, however, while casting upon him no special duty, does not extend to him the special privilege

that it does to lawyers, who are exempted from disclosure of "professional secrets," even when these relate to the commission of criminal offences.

#### *An Action for Negligence.*

Two consolidated actions of medical interest were recently heard before the Lord Chief Justice and a special jury. Mr. W. A. Bowring sued Mr. M. L. Cook to recover the professional charges for performing an operation on Mrs. Cook. Mr. and Mrs. Cook sued Mr. Bowring for damages for negligence in the operation and in the medical treatment of Mrs. Cook. Mr. Bowring's counsel, after referring to his client's qualifications, gave a brief review of the case. The plaintiff, he said, was consulted by Mr. Cook in January, 1917, about his wife's condition, and made an examination as a result of which he diagnosed the case as one of fibroid tumour incarcerated in the pelvis and advised an operation for the removal of the tumour. For the defence it was alleged that the plaintiff had advised that Mrs. Cook was not pregnant, when, in fact, she was, and that he had not completed the operation which he had advised. To these allegations the plaintiff replied that he had stated that it was doubtful whether Mrs. Cook was pregnant, and that the question of pregnancy did not affect the decision to operate. In desisting from operating he had acted in accordance with the condition of Mrs. Cook as revealed by the abdominal section. Afterwards, and as a result of his treatment, the fibroid growth in the uterus subsided, and Mrs. Cook regained her health. The jury, after two minutes' deliberation, found for the plaintiff, and judgment was entered accordingly, both on the claim and counterclaim. It seems clear that Mr. Bowring, the plaintiff in this case, acted throughout in a proper manner, and in accord with the justifiable opinions formed by him at different stages during the progress of the case. It would be intolerable for a surgeon who, during an operation, finds evidence that satisfies him that a contemplated procedure should not be carried out, nevertheless, under penalty of being cast in damages, to be forced to complete the operation "contracted for" (if the phrase be permissible) or to forego his proper fees. Mr. Bowring is to be congratulated on the swift decision of the jury in establishing an important principle.

## AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

#### *The Second Wave of Influenza.*

SINCE the first weeks of April the presence of a second wave of influenza has been manifest in Victoria. The hospital accommodation has again been severely taxed, and the disease has been more widespread in the community than before. The increase has been very marked as a result of the Easter vacation, with its overcrowding in trains and public amusements. The restrictions in force during the last epidemic were not reimposed by the Government. The Minister of Health (Mr. Bowser) was last week announced to be suffering from overstrain, and the Hon. Mr. McWhae has been appointed acting Minister. It had been generally felt that a stronger policy was required at the Health Department, and there had been some slight friction with the Medical Advisory Committee on account of certain suggestions being shelved. It is understood that the new policy will include a special medical officer, with full discretion to manage the hospital equipment and general direction of the handling of a special organisation, apart from the routine of the Board of Health. As is not unusual, the emergency hospital accommodation has proved unsatisfactory and inadequate, but the chief difficulty is stated to be the shortage of nurses. Up to the end of April there had been about 1500 deaths from influenza in Victoria. In Sydney the disease became markedly epidemic early in April. Restrictions were at once imposed, including the prohibition of all public gatherings and the compulsory wearing of masks. The course and severity of the outbreak appear to have been much the same as in Victoria. About 700 deaths have so far occurred in New South Wales.

It is impossible to say what effect the restrictions have had. Probably they have in some degree mitigated the extent of the outbreak, but at the same time there have been other evils apparent as the result of these regulations which

may have outweighed their possible good effects. Commerce has been dislocated, and much hardship has resulted from loss of employment. The coal trade has been paralysed by conflicting quarantine authorities, and the occasion has been seized upon by the seamen to demand extra wages and insurance against influenza. No definite conclusion has been reached as to the value of inoculation or masks, but the most pregnant comment on these precautions is that the public has ceased to ask for them. The Federal Director-General of Quarantine, Dr. Campston, has published an analysis of some 2000 cases in the quarantine hospitals. In the meantime the Federal department continues to issue the vaccine.

During the past week the disease has appeared in epidemic form in Queensland and South Australia, but so far not severely.

#### *The Legality of Mask-wearing.*

During the period of compulsory mask-wearing in Sydney in January, Dr. Fox, a city practitioner, refused to adopt a mask on the score that it was unhealthy. Dr. Fox was arrested and appeared before a magistrate, by whom he was committed for trial before a higher court. The State Attorney-General has decided not to prosecute, but Dr. Fox is not satisfied with this attitude, and intends to proceed against the authorities for damages.

#### *Curious Case of Snake-bite.*

A remarkable happening is reported from the Riverina. A resident of a riverside town caught a large specimen of a Murray cod, and on opening the fish discovered a live snake, by which he was bitten in the attempt to withdraw it. He was treated by a companion with a first-aid outfit and subsequently by a medical man, and suffered no further ill-result.

#### *Lodge Dispute in Victoria.*

The dispute between the Friendly Societies and the Victoria branch of the British Medical Association which has been running on since last year is still unsettled. About half of the societies have agreed to accept the Association's model agreement, but some of the others decline to come in. Meanwhile the former lodge doctors appear quite satisfied with the position, which is that they are paid by the lodge for each visit. It is said that this results in far less work than formerly, and that the remuneration is better. The Orders which stand out are hoping that, the war being over, there will be a supply of men willing to take institute places in spite of the Association's refusal to recognise institutes.

May 6th.

## NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

#### *Calcutta University Medical Schools.*

THE Senate of the Calcutta University has approved of the affiliation of the Carmichael Medical College, Belgechia, to the final M.B. standard. This is the second medical college in Calcutta to affiliate.

#### *Plague, Cholera, Small-pox, Hookworm.*

The last weekly report issued shows the mortality from plague in India as 2417 deaths against 3047 seizures. In the Bombay Presidency there were 178 deaths; in Madras, 7; in Bengal, 23; in Bihar and Orissa, 320; in the United Provinces, 706; in the Punjab, 1029; in Burma, 63; in the Central Provinces, 32; and in Mysore, 21.

By last mail a serious outbreak of cholera among the employees of the Calcutta Telegraph Office is reported. About 115 telegraphists, clerks, and messengers, including 82 Europeans and Anglo-Indians and 30 Indians, have been attacked.

There has been a considerable increase of small-pox on the Kolar goldfield during the past month, as compared with any previous month since the present outbreak. There were 100 attacks and 30 deaths, bringing the total to 275 attacks and 88 deaths since July 1st, 1918. There was a recrudescence of plague during April, after a month of immunity, and cholera has also reappeared.

Dr. J. Borland McVail, Deputy Sanitary Commissioner, has opened a laboratory at one of the Bengal mills for the investigation and treatment of ankylostomiasis among jute

mill employees. So far as has been shown to date, in spite of the excellent sanitary arrangements provided in the mills, more than 50 per cent. of the coolies are infected with hookworm disease. The treatment is being carried out by the medical staff of the mills with the advice and help of Dr. McVail and his staff.

#### *Town Planning at Lucknow.*

The Lucknow Municipal Board has resolved to guarantee the payment of the charges of a town-planning expert to enable the Lucknow Improvement Committee to secure this gentleman's return to India and his advice on the details of the various improvement schemes during next cold weather.

#### *Trooping during the Hot Weather: Educational Distractions.*

An official communiqué published in India states that some 20,000 British troops of the post-war Army are now being prepared in England for service in India. It is expected that their despatch will commence in June. It has long been recognised that during the Indian summer boredom has much to do in producing a mental and physical condition which tends to the development of disease, and steps are being taken during this hot weather to prevent the ennui and lack of interest which has been so often the curse of the soldiers' life. It has been arranged that soldiers shall be afforded interesting and congenial occupation in their leisure hours. The Commander-in-Chief is anxious that soldiers should be given opportunities for improving their general education and knowledge and, where facilities can be provided, for learning or practising a trade. The aid of local educational authorities has been freely drawn on and instruction in a large number of subjects has been arranged. The War Office, at the instance of the Government of India, has made a grant of £10,000 in aid of this educational scheme. The Government of India have also arranged to provide free passages for soldiers to and from any place in India at which they wish to spend their furlough. Last year the Government spent half a lakh on making the various homes established more comfortable for the men, and gave another half lakh to the Y.M.C.A. for a similar purpose.

#### *Red Cross Supplies for the Afghan Campaign.*

The Joint War Committee has made very complete arrangements in connexion with Red Cross supplies on the North-West Frontier for the Afghan campaign. Main depôts have been established at Peshawar, Rawalpindi, Kohat, Bannee, and Quetta, with Red Cross commissioners in charge of each.

#### *New Nursing Home.*

The Bengal branch of the Lady Minto Indian Nursing Association opened a nursing home at Salt Hill, Darjeeling, on May 1st. The home is chiefly for maternity cases, but other suitable non-infectious cases will be admitted.

June 4th.

## URBAN VITAL STATISTICS.

(Week ended June 28th, 1919.)

*English and Welsh Towns.*—In the 96 English and Welsh towns with an aggregate civil population estimated at 16,500,000 persons the annual rate of mortality, which had been 10.6, 9.9, and 10.0 per 1000 in the three preceding weeks, declined to 9.6 per 1000. In London, with a population slightly exceeding 4,000,000 persons the annual rate was 9.0, or 0.9 per 1000 below that recorded in the previous week, while among the remaining towns the rates ranged from 3.4 in West Hartlepool, 3.5 in Eastbourne, and 4.3 in Wallasey, to 15.7 in Wigan, 17.2 in Hastings, and 20.1 in Stockton-on-Tees. The principal epidemic diseases caused 133 deaths, which corresponded to an annual rate of 0.4 per 1000, and included 44 from diphtheria, 33 from measles, 31 from infantile diarrhoea, 17 from whooping-cough, and 8 from scarlet fever. Measles caused a death-rate of 1.6 in Newcastle-on-Tyne and 2.7 in Stockton-on-Tees. There were 2 cases of small-pox, 1143 of scarlet fever, and 1030 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 3, 1115, and 1085 respectively at the end of the previous week. The causes of 32 deaths in the 96 towns were uncertified, and included 3 each in Birmingham, Leicester, and Liverpool.

*Scotch Towns.*—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality, which had been 12.3, 12.4, and 11.0 in the three preceding weeks, rose to 11.5 per 1000. The 249 deaths in Glasgow corresponded to an annual rate of 11.6 per 1000, and included 12 from measles, 11 from whooping-cough, and 1 each from scarlet fever, infantile diarrhoea, and typhus. The 83 deaths in Edinburgh were equal to a rate of 12.9 per 1000, and included a fatal case of diphtheria.

*Irish Towns.*—The 107 deaths in Dublin corresponded to an annual rate of 13.8, or 1.5 per 1000 below that recorded in the previous week, and included 3 from measles and 1 each from scarlet fever and whooping-cough. The 98 deaths in Belfast were equal to a rate of 12.7 per 1000, and included 3 from scarlet fever and 1 each from diphtheria and infantile diarrhoea.

## A MONTHLY RECORD OF ATMOSPHERIC POLLUTION.

METEOROLOGICAL OFFICE: ADVISORY COMMITTEE ON ATMOSPHERIC POLLUTION: SUMMARY OF REPORTS FOR THE MONTHS

ENDING

April 30th, 1918.

May 31st, 1918.

Place.	Rainfall in millimetres.	Metric tons of deposit per square kilometre.										Place.	Rainfall in millimetres. Tr. = trace.

\* Observations suspended owing to war conditions.

"Tar" includes all matter insoluble in water but soluble in CS<sub>2</sub>. "Carbonaceous" includes all combustible matter insoluble in water and in CS<sub>2</sub>. "Insoluble ash" includes all earthy matter, fuel, ash, &c. One metric ton per sq. kilometre is equivalent to: (a) Approx. 91b. per acre; (b) 2.56 English tons per sq. mile; (c) 1 g. per sq. metre; (d) 1/1000 mm. of rainfall.

The personnel of public health authorities concerned in the supervision of these examinations and of the analytical work involved remains the same as published in previous tables. The analyses of the rain and deposit caught in the gauge at the Meteorological Office are made in THE LANCET Laboratory.

## The Services.

## ROYAL NAVAL MEDICAL SERVICE.

Temp. Surg.-Lieut. W. P. Starforth, who has been invalided on account of ill-health contracted in the Service, to retain his rank.

## ARMY MEDICAL SERVICE.

Col. Sir W. H. Horrocks, K.C.M.G., C.B. (retired pay), to be temporary Director of Hygiene at the War Office, and to be temporary Brigadier-General whilst so employed.

Col. J. Fallon retires on retired pay.

Major and Lt. Lieut.-Col. C. W. Holden, D.S.O., relinquishes the acting rank of Colonel on re-posting.

Major and Lt. Lieut.-Col. W. C. Smales, D.S.O., R.A.M.C., from Deputy Assistant Director-General, to be Assistant Director of Hygiene at the War Office.

Major-Gen. Sir W. B. Leishman, K.C.M.G., C.B., F.R.S., K.H.P., to be Director of Pathology at the War Office.

Lieut.-Col. D. Harvey, C.M.G., C.B.E., R.A.M.C., to be Deputy Director of Pathology at the War Office, and to be temporary Colonel whilst so employed.

Major A. C. H. Gray, O.B.E., R.A.M.C., to be Assistant Director of Pathology at the War Office, and to be temporary Lieutenant-Colonel whilst so employed.

Temp. Col. T. P. Legg, C.M.G., relinquishes his commission and retains the rank of Colonel.

The undermentioned Temporary Colonels relinquish their temporary commissions on re-posting: H. G. Barling, C.B. (Lieut.-Col., R.A.M.C., T.F.), J. Swain, C.B. (Major, R.A.M.C., T.F.).

## ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonels relinquishing the temporary rank of Colonel on re-posting: F. J. Brakenridge, J. S. Gallie, G. J. Houghton, H. E. M. Douglas, W. Bennett.

The undermentioned relinquish the acting rank of Colonel on re-posting: Capt. and Bt. Major W. G. Wright; Lieut.-Cols. F. McLennan, H. C. R. Hime.

The undermentioned relinquish the acting rank of Lieutenant-Colonel on re-posting: Maj. and Bt. Lieut.-Col. J. G. Bell; Majors D. P. Watson, T. H. Scott, E. C. Phelan, W. Egan, D. L. Harding, W. C. Nimmo, C. Bramhall, T. S. Blackwell, B. Johnson, G. F.

Rudkin, J. J. O'Keefe; Capt. C. M. Drew, J. W. C. Stubbs, R. B. Price, J. H. Fletcher, C. Helm, F. Worthington, E. Phillips, R. Hemphill, W. J. Dunn, R. R. Thompson, L. F. K. Way, E. W. Vaughan, H. C. D. Rankin; Temp. Capt. W. E. Hallinan.

To be acting Lieutenant-Colonels whilst commanding Medical Units: Majors R. N. Hunt, J. A. W. Webster, N. E. Dunkerton, Capt. (acting Major) W. W. MacNaught.

Lieut.-Col. G. A. T. Bray, D.S.O., is placed on retired pay.

Major W. W. Boyce, D.S.O., relinquishes the acting rank of Lieutenant-Colonel on re-posting.

To be acting Majors: Capt. and Bt. Major A. Shepherd, S. W. Kyle; Capt. T. J. L. Thompson; Temp. Capt. A. T. W. Forrester, R. H. Stevens, L. T. Giles, E. J. Pehill, J. R. Griffith, H. Findlay, R. S. Woods, J. M. Morris (whilst specially employed); Temp. Lieut. J. E. G. Calverley.

The undermentioned relinquish the acting rank of Major: Capt. and Bt. Major W. L. Webster; Capt. R. C. Aitchison, G. P. Kidd, W. J. Knight, T. J. L. Thompson, F. R. S. Shaw, D. H. C. McArthur, A. L. Stevenson, R. H. Williams, J. H. Baird, R. W. Vint, T. D. Inch, J. A. Renshaw, F. C. Chandler; Temp. Capt. J. R. M. Whigham, T. Ferguson, W. F. Morgan, R. J. B. Madden, G. B. McTearish, A. R. Esler, E. F. C. Dowling, H. J. Pickering, F. J. O. King, A. J. Dunlop, G. C. Linder, C. L. Chalk, R. B. Blair, H. B. Shepherd, F. H. Moxon, G. S. Brown, J. Rodger, E. G. Dingley, T. H. Oliver, J. W. Littlejohn, R. C. Cooke, J. L. Jackson, G. S. Murray, W. C. Horton, G. B. Elliott, W. H. Peacock, H. G. Frean, A. V. Craig, E. F. G. Ward, F. W. Jamond, C. Burnham, P. J. Chissell, J. S. Hall, T. Sturdy, H. E. Gamlen, F. H. Young, G. H. Culverwell, W. K. McIntyre, J. L. A. Groat; Lieut. (temp. Capt.) G. E. Spicer.

Late temporary Captains to be Captain: E. E. Frazer, F. Wheeler.

The undermentioned Captains resign their commissions: J. A. Andrews, J. A. W. Ebdon.

Temporary Lieutenants to be temporary Captains: L. W. Oliver, T. C. A. Sweetman.

Officers relinquishing their commissions: Temporary Lieutenant-Colonels, and retaining the rank of Lieutenant-Colonel: G. N. Stephen, G. A. Bannatyne. Temporary Major: A. F. Hurst (granted the rank of Lieutenant-Colonel). Temporary Majors retaining the rank of Major: J. G. Fitzgerald, H. S. Brander, E. F. Ackery, G. S. Samuelson, A. Robertson, C. Christy. Temporary Captains granted the rank of Major: J. B. Lowe, L. H. C. Birkbeck, J. V. Holmes, W. Haward, E. G. D. Pineo, (Acting Major) G. S. Mill, W. E. Hallinan. Temporary Captains retaining the rank of Captain: H. B. Pare, W. A.

Paterson, W. A. Rees, R. W. L. Wallace, P. O. W. Browne, W. B. Primrose, A. M. Hewat, C. G. G. Winter, A. R. F. Douglas, R. C. B. Briscoe, D. B. Leitch, W. M. McFarlane, J. Rigby, P. C. Bushnell, H. R. Wright, A. Mudie, T. G. Fetherstonhaugh, A. Farquhar, R. de V. King, A. E. Francis, E. Gardner, J. A. Loughbridge, G. S. Murray, A. A. Lees, A. M. Bayne, F. M. Auld, A. P. Ford, D. Gray, W. W. Turner, H. E. Collier, E. R. Lyth, A. H. M. Saward, L. G. Leonard, S. A. Tucker, D. W. Tacey, H. H. P. Morton, G. P. Taylor, I. M. Frazer, G. A. Ticehurst, H. S. McSorley, C. S. Stollerfoth, G. Scullard, G. B. Messenger, G. B. Crawford, W. M. Johnston, C. W. Ewing, H. Findlay, J. S. Dickson, C. O. Donovan, M. C. R. Grahame, A. T. I. Macdonald, G. R. Potter, W. Henderson, T. N. Darling, W. E. Cooper, C. C. G. Gibson, N. P. Pritchard, A. Campbell, L. Gibbons, A. W. Cochran, G. Hamilton, E. V. Hunter, H. R. W. Husbands, A. C. Giles, L. L. Hadley, C. C. B. Gilmour, D. Hardie, C. A. Joll, A. G. K. Ledger, A. J. Andrew, J. S. Taylor, D. A. Donald, J. W. Lindsay, J. O. Thomas, H. Rogers-Tillstone, J. A. Renshaw, R. Kenefick, H. V. Taylor, F. C. Trappell, K. H. Bennett, W. A. Murphy, A. E. Hallinan, B. D. Crichton, J. L. H. Paterson, V. D. O. Logan, T. Kirkwood, E. A. Donaldson-Sim, W. J. G. Johnson, H. A. Cutler, E. H. Jones, R. Calleya, W. H. Gowans, H. E. Clutterbuck, I. Feldman, W. H. Brown, W. J. G. Henderson, J. C. Bramwell, R. B. Heygate, D. S. Harvey, D. Johnston, L. W. Oliver, A. Walker, G. B. Mason, J. B. Cook, H. L. Crouk, C. Clyne, H. R. Tighe, S. G. Harrison, S. A. Day, R. M. Moore, E. P. Dark, H. C. Harrison. Temporary Lieutenants retaining the rank of Lieutenant: W. Hickey, W. F. Waugh, B. W. Lacey, R. C. Redman, H. L. Parker. Temp. Hon. Lieut. F. A. Georger retains the rank of Honorary Lieutenant.

## GENERAL RESERVE OF OFFICERS.

Major A. F. Heaton relinquishes the acting rank of Lieutenant-Colonel on ceasing to command a Convalescent Depot.

## SPECIAL RESERVE OF OFFICERS.

Captains relinquishing the acting rank of Lieutenant-Colonel on resting: W. M. Dickson, E. T. Burke.

Captains relinquishing the acting rank of Major: J. G. Ronaldson, A. F. L. Shields, W. Barclay, R. Taylor, A. R. Hill, C. R. McIntosh, P. Thornton, J. Le M. Kneebone, J. B. Cavenagh, G. G. Alderson, W. M. Blien, A. Winfield, J. B. Scott.

Captains to be acting Majors: H. Rollinson, T. Hampson.

Captains relinquishing their commissions and retaining the rank of Captain: I. D. Suttie, J. M. Courtney, R. R. Scott.

## TERRITORIAL FORCE.

Officers relinquishing their acting rank on ceasing to be specially employed: Capts. (acting Lieut.-Cols.) H. G. G. Mackenzie, J. W. Craven, W. Simpson; Capts. (acting Majors) G. P. D. Hawker, H. A. Playfair-Robertson, R. W. Swayne, R. C. S. Smith, H. B. Sproat, H. M. Fort, G. Young, J. C. Marklove, A. M. Mackay, W. L. Cockcroft, G. E. Nash, T. Graham, N. H. H. Haskins, J. C. Denver.

Capt. N. C. Rutherford relinquishes his commission.

Capt. D. W. C. Jones is restored to the establishment on ceasing to hold a temporary commission in the Army Medical Service.

Capt. C. C. Fitzgerald is restored to the establishment.

Captains to be acting Majors whilst specially employed: T. S. Worboys, N. J. Wigram, T. W. S. Paterson.

1st Eastern General Hospital: Capt. J. F. Gaskell is restored to the establishment.

1st Southern General Hospital: Capt. F. D. Marsh is restored to the establishment.

3rd Southern General Hospital: Major E. C. M. Foster is restored to the establishment.

5th Southern General Hospital: Major W. P. Purvis is restored to the establishment. Capt. (acting Major) G. H. Cowen relinquishes his acting rank on ceasing to be specially employed, and is restored to the establishment.

5th London General Hospital: Capt. (acting Major) E. M. Corner relinquishes his acting rank on ceasing to be specially employed.

3rd Western General Hospital: Major (acting Lieut.-Col.) W. M. Stevens relinquishes his acting rank on ceasing to be specially employed.

2nd Northern General Hospital: Major (acting Lieut.-Col.) W. Thompson relinquishes his acting rank on ceasing to be specially employed.

## ROYAL AIR FORCE.

Medical Branch.—Lieut. G. A. S. Madgwick is transferred to Unemployed List.

Dental Branch.—Lieut. H. H. Chapman is transferred to Unemployed List.

## AGE OF RETIREMENT IN THE I.M.S.

In accordance with a recent Royal Warrant the ages at which officers of the Indian Medical Service holding administrative appointments shall be placed on the Retired List are now as follows: Director-General 60, instead of 62; Colonels, Brevet Colonels, and general officers 57, instead of 60. The age at which Lieutenant-Colonels and Majors shall be placed on the Retired List will remain unaltered at 55.

## DEATHS IN THE SERVICES.

The late Surgeon-Commander Frederick Fedarb, R.N., who died at Southsea on May 25th last at the age of 52, was the only surviving son of the late Fleet-Engineer William Fedarb, R.N. He obtained his degree of M.B., C.M., at Glasgow University in July, 1887, and joined the Royal Navy as surgeon in 1890. He did service at home and abroad and was fleet surgeon of H.M.S. *Breadnought* during her first commission. At the outbreak of war he was principal medical officer of the Boys' Training Ship *Impregnable* at Devonport, but early in 1916 he was appointed to H.M.S. *Revenge* and served in her at the battle of Jutland. Dr. A. I. Esslemont, of Birmingham, who was with him in *Revenge* writes: "No one could have wished for a better 'chief' or more devoted friend. Dr. Fedarb was a capable administrator, well versed in all the service routine and with a sound, up-to-date knowledge of his profession. He was loved by all his shipmates, because of his quiet, inobtrusive, kind, and generous disposition, and it was a great shock to hear of his untimely death."

Colonel Sir Robert Armstrong-Jones has been appointed a Deputy Lieutenant of the county of Carnarvon.

## Correspondence.

"Audi alteram partem."

## PROFESSIONAL SECRECY IN THE EYE OF THE LAW.

To the Editor of THE LANCET.

SIR,—The attention of the council of the Medical Defence Union has been drawn to certain remarks (reported in *Berrow's Worcester Journal* of June 7th) made by Mr. Justice Bray in a case tried before him at the Worcester Assizes at the beginning of this month. The case in question was the prosecution of an unmarried woman for alleged concealment of birth. The medical man, who was called in six hours after the birth, was unable to find the body of the child, and after considering the matter decided that his duty to the patient precluded him from making any communication to the police. The police, however, upon the matter being subsequently notified to them, took a different view and adversely commented upon the doctor's conduct. He accordingly consulted the Medical Defence Union, who upheld his action in not reporting the matter to the police on the ground that had he done so he would have been guilty of a breach of professional confidence.

At the Assizes the woman was found "Not guilty." At the conclusion of the case the judge called the doctor in question into the box and addressed him, according to the report from which we quote, to the following effect:—

"..... the judge said that he saw that in the depositions the doctor had stated that, knowing that a child had been born in the room, probably recently, he did not think it was his duty to inform the police; in fact, it would have been a gross breach of professional confidence if he had informed the police, and he protested most strongly against the police reporting the matter. The judge added that in his opinion the doctor was quite wrong. There was no professional confidence in criminal cases of this kind, and it was his (the doctor's) duty to inform the police at once in a case like this. The doctor could understand the importance of it because it was possible that the child might have been still alive, and in that case it was the duty of the police to make inquiries. There was no professional confidence to prevent him giving information to the police. 'I want you to please remember that,' added the judge 'I am not blaming you for taking that view, but I think it is important that it should be known that the view you took was wrong.'"

Dr. Standing: "The Medical Defence Union instructed me that I was absolutely correct."

The Judge: "The Medical Defence Union is wrong. If you had your attention called to a patient committing the offence of cutting another man's throat, it would be your duty to go and inform the police. There is no difference between a small and a big offence."

Apart from the fact that in the case which had been tried a verdict of "Not guilty" had been returned, the council of the Medical Defence Union is unable to accept the analogy attributed to the learned judge as a fair one, or to allow that the cases are in any way comparable. The standpoint taken up by the medical profession on this subject has more than once been challenged by the legal profession. The council nevertheless maintains that the duty a medical man owes to his patient is paramount. Assured as it is on this important question the council feels it incumbent upon it to continue to advise any member seeking the guidance of the Medical Defence Union that any communications made to him by a patient and any information acquired by reason of his attendance upon such patient are confidential, and that without the authority of the patient a medical man is precluded by the accepted canons of his profession from disclosing such information to anyone. In adopting this attitude the council feels it will have the support of all those members of the profession who desire to maintain inviolate the trust and confidence which is reposed in them by their patients.

I am, Sir, yours faithfully,

JOHN TWEEDY,

President, Medical Defence Union.

4, Trafalgar-square, W.C.2, June 30th, 1919.

## HOMICIDAL INSANITY.

To the Editor of THE LANCET.

SIR,—In the interesting leading article in your issue of Saturday, June 28th, on the law and psychology of these terrible cases one point seems to me to have been overlooked. I can hardly discuss it without reference to the case recently before the courts, because certain evidence in that case has to

be cited, but I am very unwilling to enter into any controversy, still more to weight the evidence, for or against a criminal of whose case I know no more than any other reader of the newspapers.

The point I would touch upon, as far as possible in the abstract, is this: All alienists will agree that the commission of such a crime in an epileptic state is quite in accordance with experience. Many of us have seen crimes far more elaborate and systematically carried through in such states of automatism, but with this very important difference. I understand from your columns that in the case before us the criminal confessed the whole story to the constable who took him into custody. Now, in my experience of such automatic actions, criminal or indifferent, this has never been the case. In the large majority of instances in my experience the perpetrator has had no recollection whatever of the act or series of acts imputed to him; in a few he has had a vague recollection as of a dream, but would have been quite unable to tell the story plainly as a chain of facts in which he was concerned. Moreover, these few have regarded the events as hardly connected with themselves, and even then as an unfortunate accident which had befallen them by no will of their own.

I am, Sir, yours faithfully,

Cambridge, July 1st, 1919.

CLIFFORD ALLBUTT.

## EPIDEMIC PERINEPHRIC SUPPURATION.

To the Editor of THE LANCET.

SIR,—Most medical officers would, I think, agree with the remarks made by Dr. W. Pasteur in his letter on the above subject in your columns of June 21st. Perinephric abscesses containing *Staphylococcus aureus* were common in France, as they had been in civil experience before the war, and in the same way they were usually related to a small boil or other known focus of staphylococcal infection elsewhere, a focus that might have become quiescent many weeks before the development of the perinephric inflammation. In these cases, however, it does not follow that the "perinephric tissue is the site of election," as suggested by Dr. Pasteur. Perhaps the abscess has its origin more commonly in a small infective embolus within the kidney, from which pus burrows its way outwards, passing through the capsule of the kidney, and so developing into a large extra-renal collection. When abscesses arising within the kidney take such an outward course they do not spread laterally between the capsule and the kidney itself. A specimen in the Museum of University College Hospital illustrates this process, with a tiny track of yellow doubly refractive fat in the kidney, and a considerable collection of pus external to the capsule at the upper pole. Conversely the embolic abscess may rupture into the pelvis of the kidney, and be drained away so that a perinephric abscess does not develop.

More evidence from post-mortem observations is needed to determine the local origin of these perinephric staphylococcal abscesses, and to give the answers to two questions that arise in connexion with Mr. Joseph Cuning's letter—namely: (1) whether the perinephric abscess comes by outward spread of infection from an embolus within the kidney itself, or from some other focus? (2) whether the original source of the perinephric suppuration is the staphylococcal infection of subcutaneous boils, or the secondary staphylococcal infection of the respiratory tract that has occasionally been seen as a complication of influenza, and might lead to an epidemic of such abscesses at a time when complicated influenza is rife?

It is certain that the ordinary or sporadic perinephric abscess in France was the sequel of boils, just as pyæmic abscesses in other tissues (for example, in the myocardium causing suppurative pericarditis) or virulent staphylococcal septicæmias have occasionally been seen with such a history, when there was no possibility of their having been caused by a staphylococcal infection of the lungs coincidentally with an attack of influenza. Among these there is one group of cases of very considerable interest, where the staphylococcal infection from boils enters the lungs directly and produces a picture somewhat like that of an original influenza. Such cases were not, to my knowledge, frequent in civil experience, but several pathologists saw them at autopsy during the war in France. A description of these cases was written in 1916 by Captain

H. W. Kaye, R.A.M.C., but its publication was forbidden at the time by the military censorship. They presented the signs of acute pulmonary disease with profound toxæmia, and were clinically diagnosed at first as "pneumonia." Post-mortem examination discovered innumerable small acute abscesses in the lungs, these being related to the lung-vessels and not to the bronchi. An actively inflamed boil was generally found close to some tributary of the superior vena cava, with pus tracks radiating into the tissues, and staphylococci had been present in the blood during life. Curiously, no embolic abscesses were observed outside the area of the lungs. Death usually results in these acute pulmonary cases, where the resistance to staphylococcal infection must be very low; but I have seen an example of double staphylococcal empyema, that may have belonged to this group, and in which recovery followed upon drainage of the pleural cavities. It is an extraordinary fact that in the special skin hospitals at the base, where acute and chronic boils were very numerous, deeper complicating abscesses were practically never seen. The proportion of cases with boils, in which such abscesses occur, must therefore be very small. Nolf, Bossaert, and Colard, however (*Archives Médicales Belges*, Janvier, 1918), have insisted that a passing infection of the blood and of the urine by staphylococci is more frequently present than has been generally recognised.

Staphylococcal blood infection as a complication of true influenza was described by Patrick and Garrod in THE LANCET of Jan. 25th, 1919. It is quite probable that a "boil" in the lung as a complication of influenza may lead to all the various staphylococcal abscesses at a distance that are known to follow a subcutaneous boil, and that there may in reality be such an epidemic as has been suggested by Mr. Cuning.

I am, Sir, yours faithfully,

T. R. ELLIOTT,

Late Colonel, A.M.S.; Consulting Physician, B.E.F.

University College Hospital, July 1st, 1919.

To the Editor of THE LANCET.

SIR,—I shall be very glad if you can spare me a little space for a few words further on this subject. Neither Sir Thomas Horder nor Dr. Pasteur see any reason to suppose that the condition of perinephric suppuration has any causative relation to influenza, but consider it to be a staphylococcal pyæmia. It may smack of the distinction without a difference type of argument if I desire to state that I feel it wrong to have expressed my opinion that "the recent epidemic of influenza was the primary disease in these cases of perinephric suppuration," and that I ought to have said as my actual opinion "associated with a primary influenzal infection." But this substitution affords me the opportunity to meet Dr. Pasteur's weighty objection that cases occurred in his experience long before the influenza epidemic manifested itself. It is, of course, admissible that during an epidemic any sort of otherwise unexplained pyrexia is conveniently included, and my assumption that two of my cases of perinephric suppuration occurred in patients who had suffered from definite attacks of influenza is justly criticised. But even at the risk of being wearisome I would like to reiterate my opinion that in these cases influenza exerted a determining influence.

It will be recalled that the secondary complications (the dreaded "influenzal pneumonia" and influenzal septicæmia) would appear to be due to organisms whose activity is exalted or altered by a primary invasion by *B. influenza*. It will be remembered, also, that the condition of "purulent bronchitis," originally regarded as a sort of pathological entity, was shown subsequently to be primarily an influenzal infection, and these cases occurred fully two years before the actual epidemic of influenza.

In accepting, then, the authoritative pronouncements of Sir Thomas Horder and Dr. Pasteur, I venture to claim some justification for my support of Mr. Cuning that the condition of perinephric suppuration was associated with influenza, although I see that I was in error in using the term "epidemic" in this connexion.

I am, Sir, yours faithfully,

ADOLPHE ABRAHAMS.

Connaught Hospital, Aldershot, June 28th, 1919.

## INDUSTRIAL MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—The leading article in THE LANCET of June 21st and the special article in to-day's issue are most timely and apt. Unfortunately, during the war, under the plea of economy, the Government abolished the statutory inquiry by the certifying factory surgeon into the cause and prevention of certain accidents by machinery. These investigations gave the certifying surgeon a very real and intimate knowledge of the working conditions and danger-points in all the factories within his district. This experience familiarised him with the temperature, moisture, dustiness, weight-lifting, periods of rest and activity, and the strains and stresses peculiar to each particular process, also the mental and bodily exertion demanded of the workers. Such knowledge is essential to a medical man who has to estimate and certify that young boys and girls are suitable or fit to be employed in a particular occupation. The certifying surgeon of some years' standing still retains in his memory the danger-spots and unwholesome parts in mill and workshop. It is surely highly important that this close practical intimacy should be restored or other equally real routine of duty inside the factory should be given to newly appointed certifying surgeons to enable them to judge wisely the suitability of our youth to bear the hazards of fatigue, and so minimise the ever-present risk of accident and ill-health.

Unfortunately, this branch of the factory department has been hampered and its value to the community made less efficient for many reasons. A recently appointed officer has often an insufficient acquaintance with the principles and details of industrial hygiene. A course of instruction in this subject is most desirable of those selected for these posts. He should have more executive authority in enforcing his recommendations and provisional certificates. More supervision and standardisation of his duties are required. The public must be better educated into the necessity and utility of this and allied services so that the risk of clashing is avoided between parental gain, individual liberty, and the welfare of the rising generation. Lastly, the sixpenny fee should be abolished. To expect that a satisfactory examination can be made and a certificate given for such a sum is the abnegation of common sense and experience. Reforms on the lines above indicated and further regulations which your articles and modern opinion demand are, I believe, appreciated by the heads of the Factory Department. If carried out they would rapidly build up a competent industrial medical service throughout the country. I am, Sir, yours faithfully,

Wigan, June 28th, 1919.

R. PROSSER WHITE.

## DETOXICATED VACCINES.

To the Editor of THE LANCET.

SIR,—I was very much interested in the excellent paper by Dr. David Thomson on detoxicated vaccines in THE LANCET of June 28th. As I have been working on very similar lines for over a year I should like to raise a few points and offer a few suggestions upon the subject.

1. *As to the nature of the toxin removed.*—Dr. Thomson states that this is the endotoxin, though the impressions gained at the present stage of my investigations do not suggest this. I have no evidence that it is comparable to the exotoxin of *B. diphtheriae*, *B. tetani*, &c., but I have considerable evidence that it is situated outside the organism and it can be removed without causing autolysis of the organisms. From the rough chemical investigations made it appeared to be a nitrogen-containing fat or lipid, and at present I picture it as an external toxin.

2. *As to the nature of the precipitate.*—In addition to the stroma of the organisms the precipitate contains another substance, which, I believe, is of considerable importance in the production of antibacterial substances.

3. Dr. Thomson does not offer an explanation of the rapid production of immunity following administration of detoxicated vaccine. It is difficult to understand how the body can be stimulated to produce antibodies in less than 24 hours, and yet in acute pneumococcal infections a corresponding sensitised vaccine will give definite evidence of immunity production in from six to eight hours, and I have recently modified my method of making detoxicated vaccines which apparently give similar results.

4. I agree with the editorial comment that more evidence must be produced before the complement-deviation reaction

can be taken as an indication of the resulting immunity titre. I should regard these reactions as evidence of bacterial substances in the blood stream, but not necessarily immune bodies.

5. *Suggestions as to dosage and possible dangers.*—About a year ago I was preparing detoxicated vaccines which I think would be identical with those described by Dr. Thomson, though the technique used was different, and I investigated the vaccine so produced from the following standpoints: (a) To determine whether it was non-toxic and harmless to normal individuals and animals; (b) to determine the effects when given during, or at varying intervals before, infection with the corresponding organism; (c) to determine whether it was superior to an ordinary vaccine in producing immunity.

Without going into details, the conclusions arrived at were that for many organisms, such as streptococci, pneumococci, &c., the detoxicated vaccine was for practical purposes harmless and non-toxic, except in cases of severe general infection, as, for example, streptococcal septicaemia. There are also organisms which may produce a severe toxic effect, and *B. dysenteriae shiga* is an example. Rabbits appear to tolerate, without showing any signs of discomfort, enormous doses of a detoxicated virulent strain of pneumococcus, while they are susceptible to comparatively small doses of Shiga prepared by the same method. The signs and post-mortem findings do not constitute the entire group of typical Shiga infection, but the animal nevertheless rapidly dies.

Dr. Thomson has presumably worked out the results principally with the gonococcus, and in infections with this organism evidences of general toxæmia are usually slight. Until the nature of the immune bodies produced by this form of vaccine has been determined—and I think they will be found to be of a variety not usually produced—I should like to put forward the following suggestions as to the use of this form of vaccine in general infections. I have had no experience with it in gonococcal infection, but have used it a good deal in other infections and carried out a number of animal experiments.

(a) *As to dosage.*—I should suggest its use more on the usual lines of administering sensitised vaccines, and the method I employed was to give 500, 1000, and 1500 million on three consecutive days, followed by a dose of 1500 million every fourth or fifth day. Also, until we know more about the exact results, I should regard 2000 million as a maximum dose, at any rate in severe infections. This suggestion is based upon conclusions that because a given dose is harmless in a normal individual or in one suffering from a chronic infection, it does not necessarily hold that the same applies to a patient suffering from a severe acute infection. I think it possible by the rapid production of antibacterial substances to produce a condition analogous to "sterile death" in these cases. Under these circumstances the disease might be cured, but the patient would not survive. Also surplus vaccine given to a patient in extremis might unnecessarily add to the existing severe toxæmia.

(b) *When using a previously untried organism.*—I should suggest commencing with relatively small doses. I have inoculated myself with several thousand million detoxicated pneumococci without any local or general ill-effects; but I should not like to have to try a similar initial dose of *B. dysenteriae shiga*.

If used, while bearing in mind the above two factors, I am sure that vaccines prepared as described so ably and fully by Dr. Thomson will be found to be very much more effective than ordinary vaccines. I think, however, that the detoxication process is not quite complete, and I have recently evolved a modification which promises to be a more complete imitation of sensitisation. These findings I hope to publish shortly when completed.

I am, Sir, yours faithfully,

S. G. BILLINGTON, M.B. Lond.,

Stoke-on-Trent, June 30th, 1919. Late Temporary Captain, R.A.M.C.

**THE GILCHRIST SCHOLARSHIP FOR WOMEN WAR WORKERS.**—The Gilchrist trustees offer through the council of the London (Royal Free Hospital) School of Medicine for Women a special scholarship tenable at the Medical School by a woman who has served under an organisation directly connected with the war during not less than three years since August, 1914. The scholarship is of the value of £50 per annum for five years. Applications should reach the warden and secretary of the Medical School, 8, Hunter-street, Brunswick-square, W.C.1, not later than July 12th, from whom the necessary form of application and all particulars may be obtained.

## Obituary.

R.T. HON. SIR JOHN MCCALL, M.D., HON. LL.D., GLASG.

Sir John McCall, who died of pneumonia on June 28th, was better known as a statesman than as a doctor. He was, however, a graduate of medicine in the University of Glasgow, taking his M.B. degree there in 1881 when only 21 years of age, and it was not until 1888 that he entered the political world as a Member of the Tasmanian House of Assembly. He carried his medical experience and qualifications with him in his political career, and in 1903, when he became Chief Secretary, he was responsible for an entire reorganisation of the Tasmanian Department of Health. In 1904 he became M.D., and five years later he was appointed Agent-General for Tasmania in London, an appointment which he held with conspicuous distinction until the time of his death. He was created a Knight Bachelor in 1911 and received the K.C.M.G. in the last Birthday Honours, no doubt as a recognition of the great services he rendered in promoting the welfare of Australian troops in hospital or billeted in this country. He allowed himself practically no recreations, his whole time being placed at the disposal of his fellow Australians in need of sympathy or advice. His career as a medical statesman is finding a worthy reproduction in that of his son, who is now district medical officer and medical officer of health in Leonora, West Australia.

EDWIN GREAVES FEARNSIDES, M.D., B.C. CAMB.,  
B.Sc. LOND., F.R.C.P. LOND., M.R.C.S. ENG.,

MEDICAL REGISTRAR TO THE LONDON HOSPITAL; AND ASSISTANT  
PHYSICIAN TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS,  
MAIDA VALE.

A BRILLIANT medical career has been cut short by the death of Dr. Edwin G. Fearnside, which took place on June 26th as the result of a boating accident. Dr. Fearnside, who was born in 1883 at Horbury, Yorks, was the son of the late Joshua Fearnside, and was a successful student at Cambridge, the London Hospital, and at Berlin. In 1902 he was senior scholar at Trinity Hall, Cambridge, and graduated in 1906 with a first-class in the natural science tripos. In the same year he won the Anatomy and Physiology prize at the London Hospital, having in the previous year graduated B.Sc. Lond., taking first-class honours. In 1908 he proceeded to the M.B. and B.C. degrees, and also obtained the Conjoint Diploma of the London Royal Colleges while holding the appointments of clinical assistant to out-patients and house physician to the London Hospital. In the following year he became receiving-room officer, resident anaesthetist, and clinical assistant to the ophthalmic department and at the Hospital for Sick Children, Great Ormond-street, clinical assistant. He proceeded to the M.R.C.P., and after holding the position of house surgeon to the London Hospital in 1910, he became medical registrar a year later. In 1915 he was deservedly elected, on a very short probation, a Fellow of the Royal College of Physicians of London. He was a Beit Memorial Research Fellow and had been assistant examiner in medicine for the University of London. Late Major in the Royal Air Force, he was neurologist to the Hospital for Officers of the Royal Flying Corps, and resident medical superintendent of the Home of Recovery, Highfield. He had recently become a valued editorial writer in our columns.

As assistant physician to the Hospital for Epilepsy and Paralysis, Maida Vale, Dr. Fearnside found an opportunity of perfecting his knowledge of neurology, a subject with which he was specially interested in addition to general medicine, and he contributed much to the literature of both subjects. He was the author of the articles "Eosinophilia" in Allbutt's System of Medicine, "Parasyphilis of the Nervous System" (with Drs. Head, Fildes, and MacIntosh) in *Brain*, 1913, and (with Dr. Head) of "Clinical Aspects of Syphilis of the Nervous System in the Light of Wassermann Reaction and Treatment with Neosalvarsan," 1914, as well as of "Intracranial Aneurisms" and "Innervation of the Bladder" in subsequent years. In 1914 he read a paper before the Electro-therapeutical Section of the Royal Society of Medicine on Diseases of the Pituitary Gland and their Effect on the Shape of the Sella Turcica, which was published in THE LANCET of July 4th, 1914, and upon which valuable

contribution to an important study we commented editorially in the same issue. To the Section of Neurology of the Royal Society of Medicine, among other valuable papers, he contributed one on the Essentials of Treatment of Functional Nervous Diseases in Soldiers, which was reported in our issue of March 23rd, 1918, and which well illustrates his way of approaching a difficult practical subject.

We have said enough to show that by the untimely death of Edwin Fearnside the science and practice of medicine, as well as the institutions with which he was associated, suffer a heavy loss, but above all things Dr. Fearnside was a fine type of the institutional officer. "He was," says the secretary of one of his hospitals, "a great and tireless worker, and he allowed nothing to stand in the way of his hospital work. He was devoted to his patients, and particularly can this be said of him during the war, when the functional side of nervous disease became an urgent matter. During his tenure of office as an assistant medical officer at Springfield War Hospital, and whilst medical superintendent of 'Highfield,' Golders Green, he worked tirelessly first for serving soldiers at Springfield, then for pensioned soldiers, and afterwards for officers of the Royal Air Force at 'Highfield.' As a colleague he was always prepared to place his

EDWIN GREAVES FEARNSIDES, M.D.

services at the disposal of others, and his generous nature made him a host of friends amongst his patients and colleagues, all of whom will mourn his death. When he relinquished his commission as a major in the Royal Air Force Medical Service on the 31st May and left London for a holiday he was a tired-out man for the moment, but no one can doubt that he had a great future before him."

A. S. MacN., an intimate friend, in an eloquent tribute to Fearnside's memory, dwells also in particular upon the value of his work at the Home of Recovery. "At Golders Green," he writes, "Fearnside was most successful. Many an ex-soldier and ex-airman who was brought back to health and mental sanity through Fearnside's instrumentality will feel personal regret for the loss of the doctor who first took the trouble to understand them. Fearnside was an able thinker. With his chief and friend, Dr. Head, he was a pioneer in the interpretation of the 'new neurology.' He was never tired of teaching that in medicine the individual was to be considered and not the disease. His high intellectual gifts were recognised by the College of Physicians in his election to the F.R.C.P. at an unusually early age. Though young in years, already he had achieved much. Had life been spared to him he would have ranked as one of our foremost thinkers and physicians. In conversation he often sketched out proposals for treatises the skeleton-plans of which were marked by originality of thought, and which were

new and stimulating in suggestion. One, I remember, was to give us an entirely new conception of 'pain.' These, alas, will now never be written. *Dis aliter visum!* Fate snatched him from us at the zenith of human happiness, when his life seemed rich with the promise of all that was good."

GEORGE WILKS, M.C., M.B. CANTAB., M.R.C.S., L.S.A.,

LATE MASTER OF THE SOCIETY OF APOTHECARIES AND PHYSICIAN-  
IN-ORDINARY TO THE LATE DUKE OF EDINBURGH.

Dr. George Wilks, who died on June 11th at his residence, Ashford, Kent, aged 79, was a native of the town in which he lived, and the elder son of George Frederick Wilks, of the near-by village of Charing, where his father and other members of the family were medical men before him. He was educated privately until the age of 13, when he went to King's College, London. He afterwards studied in Dresden. Returning to England, he entered Trinity College, Cambridge, where he graduated B.A. in the Classical Tripos in 1863. For two years he was a pupil of Sir George Murray Humphry at Addenbrooke's Hospital, and afterwards a pupil of Sir James Paget at St. Bartholomew's Hospital. In 1867 he proceeded to the M.C. degree, taking also the M.R.C.S. Eng. and the L.S.A. He then started practice with his father at Ashford, and carried it on alone from the time that his father died till 1886, when he was joined in partnership by Mr. E. G. Colville. From 1907 to 1908 he was Master of the Society of Apothecaries of London, and his appointment as physician-in-ordinary to the late Duke of Edinburgh led to his attendance on the Duchess at the birth of the present Queen of Roumania and the Princess Beatrice of Orleans.

Dr. Wilks took an active interest in municipal and social matters, was a prominent Freemason, and a Vice-President of the League of Mercy. As an active supporter of the Ashford Cottage Hospital he helped to free that institution from debt, and in 1906 was presented with a handsome silver tray and a cheque for £150 in recognition of his services to the institution as medical adviser, honorary treasurer, and secretary. With his customary generosity he handed the cheque to the hospital for the formation of an emergency fund.

MICHAEL JOSEPH MCCARTAN, L.R.C.P. & S. IREL., J.P.

THE death took place on June 27th at his residence at Rostrevor, co. Down, of Mr. Michael McCartan. Born in 1857, he was the youngest and only surviving son of the late Mr. Thomas McCartan, J.P., of Baymount, Rostrevor. In 1883 he became a Licentiate of the Royal Irish Colleges, and began practice in Newry, where he also was a member of the Town Commissioners; and in 1899, when that body was changed into the Newry urban council, he was elected chairman, a position he held until his retirement in 1901, when, owing to the state of his wife's health, he was obliged to go to reside in Jersey. From 1897 to 1901 he represented the Newry town board on the Carlingford Lough Commissioners, and he was an original member of the Newry Port and Harbour Trust. In 1893 he was made a justice of the peace for county Down. In 1901, in recognition of his valuable services to Newry, he was the recipient of a public presentation, which took the form of an address and an oil portrait, a replica being placed in the council chamber of the Town Hall. In 1909 he went to reside in Rostrevor, and was in that year appointed dispensary officer of the Rostrevor district, as well as medical officer of health; he was also consulting medical officer of health of the Kilkeel rural district council, and attendant on the Royal Irish Constabulary in Rostrevor, and certifying factory surgeon. All these positions he held at the time of his death. He was buried on June 29th at the old family burying-ground, Kilbroney, Rostrevor. Mr. McCartan was a skilful doctor, a shrewd man of affairs, and greatly respected by his medical brethren and his patients.

DISPENSARY DOCTORS' SALARIES IN IRELAND.—After an acrimonious discussion the Ballymena board of guardians, on June 28th, rescinded all previous resolutions on the subject, and fixed the scale of salaries for medical officers of the union at a minimum of £120 per annum, rising by annual increments of £20 to £200, except in the case of the Ballymena dispensary district where the maximum was fixed at £220.

## Medical News.

UNIVERSITY OF OXFORD.—At examinations held recently the following candidates were successful:—

SECOND EXAMINATION FOR DEGREE OF BACHELOR OF MEDICINE.

*Materia Medica and Pharmacology*.—W. H. Butcher, St. John's; T. Y. Cathrall, Trinity; J. T. S. Hoey, Jesus; J. G. Johnstone, St. John's; H. A. Osborn, New; D. B. Pauw, Trinity; H. L. Rayner, Balliol; M. E. Shaw, New; W. F. Skaffe, Trinity; and N. F. Smith, Balliol.

*Pathology*.—T. A. Brown, Exeter; C. K. J. Hamilton, Lincoln; J. T. S. Hoey, Jesus; H. A. Osborn, New; and H. L. Rayner and N. F. Smith, Balliol.

*Forensic Medicine and Public Health*.—L. G. Brown, Balliol; W. H. Butcher, St. John's; F. B. Chavasse and W. T. Collier, Balliol; F. G. Hobson, New; B. G. von B. Mellé, Brasenose; O. B. Pratt, Christ Church; N. F. Smith, Balliol; and C. P. Symonds, New.

*Medicine, Surgery, and Midwifery*.—L. G. Brown and F. B. Chavasse, Balliol; J. C. Dixey, Brasenose; F. G. Hobson, Queen's; O. B. Pratt, Christ Church; N. F. Smith, Balliol; and C. P. Symonds, New.

MASTER OF SURGERY.

R. O. Ward, Queen's.

UNIVERSITY OF DURHAM; FACULTY OF MEDICINE.—At examinations held recently the following candidates were successful:—

THIRD EXAMINATION FOR DEGREE OF BACHELOR OF MEDICINE.

*Materia Medica, Pharmacology, and Pharmacy; Public Health; Medical Jurisprudence, Pathology, and Elementary Bacteriology*.—

Samuel Eric Hill Anderson, John Stratton Brogdon, James Struthers Clark, Edward Thomas Colville, Oliver Colville (second-class honours), Robert Collinson Davison, Dorothy Amatt Dixon (second-class honours), Thomas William King Dunscombe, Eskander Girgis, Barbara May Gringing, Donald Falconer Hocken, William Ewan Douglas Hodgson, Harold Holtby, Henry Norman Clarence Jaffé, George McCoill, Robert Turnbull Easton Naismith, Carl Damien Newman, Thomas Swinhoe Severs, Louis William Studdy, William Arthur Tweddle, William Christopher Wardle, and Edith Short Williamson.

THIRD EXAMINATION FOR LICENCE IN DENTAL SURGERY (L.D.S.).

*Anatomy, Physiology, and Histology; Dental Anatomy, Dental Histology, and Dental Materia Medica*.—Montague Olswang and Gainsford Reed.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—The following candidates have passed the Final Dental Examination and have been granted the diploma L.D.S. R.C.S. Edin.:—

Euphemia Ross Hadley, Thomas Stewart Tait, Andrew Finlay Readdie, and Edward Louis Adendorff.

ROYAL SOCIETY OF ARTS.—The council of the Royal Society of Arts have awarded the society's silver medal for the following papers read before the society during the past session:—

Edward C. de Sgundo, A.M.Inst.C.E., "The Removal of the Residual Fibres from Cotton Seed and their Value for Non-textile Purposes."

Sir Frank Heath, K.C.B., secretary, Department of Scientific and Industrial Research, "The Government and the Organisation of Scientific Research."

Walter Leonard Lorkin, A.M.I.E.E., "Electric Welding and its Applications."

W. Norman Boase, C.B.E., "Flax—Cultivation, Preparation, Spinning, and Weaving."

Brigadier-General Lord Montagu of Beaulieu, C.S.I., "Aviation as Affecting India."

Professor John Cunningham McLennan, O.B.E. Ph.D., F.R.S., "Science and Industry in Canada."

ST. THOMAS'S HOSPITAL ANNUAL DINNER.—The dinner of past and present students of St. Thomas's Hospital will take place on Wednesday, Oct. 1st, at the Connaught Rooms, Great Queen-street, W.C., Sir George Makers, G.C.M.G., in the chair.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held at Queen Anne's Gate Buildings, Westminster, on June 18th, with Sir Francis H. Champneys in the chair. Two midwives were struck off the Roll, the following charges, amongst others, having been brought forward:—

A case being one of abortion and the patient suffering from excessive bleeding the midwife did not explain that the attendance of a registered medical practitioner was required, as provided by Rule E. 21 (2 and 3); the midwife neglecting to take and record the pulse and temperature of the patient at each visit, as required by Rule E. 14; neglecting to enter her records of pulse and temperature in a notebook or on a chart, carefully preserved, as required by Rule E. 14, and falsely denying all knowledge of the case when questioned by the Inspector of Midwives, and making false statements as to the entries in her register of cases. Being in attendance as a midwife at a confinement, the case being one of twins, and medical aid having been sought for both children, the midwife neglected to notify the Local Supervising Authority thereof, as required by Rule E. 22 (1) (a); one of the twin children suffering from inflammation of, and discharge from, the eyes, she did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E. 21 (5), and medical aid having been sought for the said child she neglected to notify the Local Supervising Authority thereof, as required by Rule E. 22 (1) (a).

**EPSOM COLLEGE.**—The sixty-sixth annual general meeting of the Governors of Epsom College was held on June 27th at 37, Soho-square, W., when Sir Henry Morris, the treasurer, presided, and was supported by a large number of governors. The treasurer moved the adoption of the report for the past year, which showed that there was a moderate surplus on the income and expenditure account, though this could only be looked upon as a temporary saving, in view of the fact that only pressing repairs had been carried out at the College owing to the Government's restriction on building, the lack of labour, and the high cost of materials. A bequest of £5000 less £500 duty was noted from the late Mr. Henry Duncalfe for the purpose of establishing annuities for "the daughters of medical practitioners who shall be and so long as they shall remain unmarried and who shall have attained the age of 50 years." The pensions will be of the annual value of £30, and the election remains in the hands of the council of the College. The report further stated that the War Memorial Fund, instituted by the Old Epsomian Club with a view to rebuilding the nave of the chapel in harmony with the new chancel and to place in it a suitable monument bearing the names of old Epsomians and Epsom masters who have sacrificed their lives in the war, had not been responded to so generously as the committee of the fund expected. It was pointed out that contributors to this fund would be given the same voting privileges as those allotted for contributions to the Royal Medical Foundation of the College. One of the vice-presidents of the College, Dr. Ralph Gooding, had established, said the report, a prize for annual competition amongst the students of the College to be called "The Ralph Gooding Botany Prize." The report concluded by stating that over 800 Old Epsomians had served with the Forces, and that in the Roll of Honour were included 122 who had died on active service. 72 Old Epsomians had been mentioned in despatches, 1 was awarded the Victoria Cross, and 83 received decorations and honours for war services.

In proposing the adoption of the report the Chairman drew attention to the fact that the bequest from the late Dr. Strong, which had been reported in the press recently, was left for the specific purpose of increasing pensions and for providing new pensions. He also mentioned the need of special gifts for other purposes, such as building, repairs, reducing the mortgage, making good the depreciation of stocks, and providing for increases in masters' salaries. The expenditure in future on the last-named item would be greatly increased owing to the provision of higher salaries for masters.

The meeting was concluded by a unanimous vote of thanks to the Chairman for presiding.

**THE Royal Society of Medicine** has nominated Sir Humphry Rolleston as representative of the society on the panel to be appointed by the Minister of Health to assist him in selecting a Consultative Council.

**THE RESEARCH DEFENCE SOCIETY.**—This society held its annual general meeting on June 26th at the house of the Medical Society of London, 11, Chandos-street, Cavendish-square, where it now has its office and official address. Lord Knutsford presided, and the meeting was very well attended. A short address was given by Sir Anthony Bowlby on Experimental Medicine and the Sick and Wounded in the War. Sir Frederick Macmillan proposed, and Captain Walter Elliot seconded, a vote of thanks to him. The committee's report gives an account of the society's lectures and of the measures taken against the Dogs' Protection Bill. "We have reason to congratulate ourselves on the strength of the opposition to the Bill in the newspapers, in the House of Commons, and at the Home Office; and we may fairly claim some of the credit for it. Certainly, ten years ago, neither the Government nor the press would have been so outspoken against a Bill which very naturally appealed to those who had not studied the subject." The honorary treasurer's report stated that the finances of the society were in a satisfactory state. "We have been able, after meeting all our expenses, to invest £500 in War Stock. This, added to our previous holding—amounting in all to over £1500—constitutes a valuable reserve to meet any extra expenditure which the work of the society may necessitate." Captain Walter Elliot, M.P. for Lanark, has consented to be assistant honorary secretary, working with Mr. Paget as honorary secretary. The committee greatly hope that some of the society's members will offer to give one or two simple, popular lantern lectures during the coming autumn and winter. There is a steady demand for lectures on such subjects as the work of Pasteur and of Lister, the recent discoveries in preventive medicine, and the medical and surgical facts of the war. It is quite simple lectures that are especially wanted in our small towns, our villages, our schools. The Research Defence Society has a good collection of lantern slides, and the honorary secretary will be very glad to be of any use to anybody who will give a lecture of this kind.

## Parliamentary Intelligence.

### NOTES ON CURRENT TOPICS.

#### *The Select Committee on Pensions.*

Field Marshal Sir DOUGLAS HAIG was a witness before the Select Committee on Pensions at the House of Commons on Tuesday, July 1st. In the course of his statement he called attention to the medical boards. In some cases, he said, the members of the board were ignorant of the actual diseases suffered. In others they were lacking in all sympathy and generosity. There was no uniformity in their decisions, and some treated every wretched individual who appeared before them as a malingeringer. He strongly advised the appointment of a selected combatant officer to act as assessor, so as to produce some confidence in the decision. Again, in some cases the disability was reassessed at the Ministry of Pensions to the individuals disadvantage. That this should be done without the individual being seen or heard was contrary to all ideas of British justice. He urged a more generous and sympathetic treatment to all who suffered from gas poisoning, shell shock, and neurasthenia. It was admitted that their suitable employment was no easy matter. Employers were shy of giving them appointments. The most piteous appeals brought to his notice cried for an immediate reform in the method of treatment.

### HOUSE OF COMMONS.

THURSDAY, JUNE 26TH.

#### *Ministry of Health Appointments.*

Lieutenant-Colonel DALRYMPLE WHITE asked the Prime Minister whether, as regards appointments to the new Ministry of Health, consideration would be given to the applications of officers and men who had served throughout the war, even though they might be slightly over the age hitherto laid down for admission to the Civil Service?—Mr. STANLEY BALDWIN (Financial Secretary to the Treasury) replied: The normal age limits for candidates for Civil Service appointments fixed before the war have been extended so that candidates at the competitions now being held under the reconstruction scheme who have served in the Forces may deduct from their age the full period of the war. This extension will apply to candidates for posts in all Departments alike, and I am not prepared to make any special provision for the new Ministries.

#### *Hospital at Chepstow.*

Mr. H. JONES asked the Parliamentary Secretary to the Shipping Controller whether the hospital built at Chepstow in connexion with the national shipyards, at a cost of about £100,000, was now empty and derelict; whether such hospital was built by contract; if so, who was the contractor; when was the work commenced; and on what date was the contract signed?—Colonel LESLIE WILSON replied: The hospital at Mount Pleasant, Chepstow, has been taken over by the Ministry of Pensions as from May 31st last for the treatment of neurasthenic and other cases. The building was erected by contract by Messrs. Henry Boot and Sons, and was commenced in December, 1917. The contract was finally signed on August 2nd, 1918.

#### *National Insurance Bill.*

Major ASTOR, Parliamentary Secretary to the Local Government Board, presented a Bill to alter the rate of remuneration for the purposes of exception from insurance under the National Insurance Acts, 1911 to 1918, and for purposes connected therewith. The Bill was read a first time.

FRIDAY, JUNE 27TH.

#### *Dogs' Protection Bill: Third Reading Negatived.*

On the motion for the third reading of the Dogs' Protection Bill proposed by Sir F. BANBURY,

Sir WATSON CHEYNE moved as an amendment that "This House declines to proceed further with a measure which would impose an unnecessary and vexatious obstacle to medical research." He said that he had not as yet spoken in the House on this Bill. He quite recognised the value of the amendment moved on the report stage as an alternative to the Bill itself, but the more he looked at the amendment the more he felt that it introduced a very great obstacle to research in these matters. It seemed a very little thing to get an additional certificate, but he would show that it really was not, and the very matter of getting this additional certificate was an obstacle which ought not to be introduced at the present time. From another point of view he did not think this Bill should be proceeded with, and that was because it involved a very grave censure upon a large body of honourable men and a great profession for which there was no justification whatever. He did not think the House realised what an

amount of obloquy had already been thrown upon men who were only trying to do something which might be of great use to mankind and science. The Bill as it stood practically stated that the House had gone carefully into the matter of all these accusations, and it implied that cruelty was being practised, that the medical profession delighted in torture, and that they could not be trusted in the matter of animals.

Sir F. BANBURY: That is not in the Bill.

Sir WATSON CHEYNE said that he asserted that that was what it implied; and for these reasons it was alleged that it was necessary to tie the hands of medical men still further, even though such a proceeding might involve a serious loss to humanity. He could speak of this matter from first-hand knowledge, because at one time he held certificates and licences for a number of years and later on in his career he became one of those who had the responsibility of signing certificates. Having sketched with some detail the rise of the study of bacteriology in connexion with clinical medicine and research, and the restrictions put upon animal investigations in the past, Sir Watson Cheyne protested against the further restrictions proposed by the Bill, which must result in lost enthusiasm and helated work. He gave a vivid picture of humanitarian exaggerations, illustrated to the House what an "animal experiment" really meant, showing why dogs were sometimes needed in the continuation of research, why post-mortem examinations could not take the place of experiments, and why many experiments, which had proved of immense value to the world in the past, might have been prevented by difficulties in the obtaining of certificates such as were foreshadowed in the Bill. The position then might be reached that we should have to go to Germany for our discoveries.

#### *Further Criticism of the Bad Effects of the Bill.*

Sir P. MAGNUS seconded the amendment. He said that the Bill proposed to impose further restrictions on a measure of great and fundamental importance to the health of the country. If it were for no other reason than preventing any reproach which was implied in the very title of the Bill attaching to the distinguished medical men who performed these experiments, that would be an amply sufficient reason for rejecting the Bill. If the Bill was passed in the form in which it stood, ignorant people who subscribed to the antivivisection funds would go about saying that the Bill had been passed in the House of Commons for the further restriction of experiments on animals, and that although it was true that the Bill had been passed with slight amendments, nevertheless a Bill had been passed saying that experiments on animals were cruel and inhuman. That would produce a very bad effect. Unless the Bill were rejected the friends of antivivisection would say that they had gained something from its passing, and the large sums of money which were absolutely wasted in the propaganda against vivisection would continue to be wasted, and the sums of money contributed by sympathetic and benevolent old ladies of both sexes which might be expended on founding research laboratories would be expended in the huge advertisements which met one wherever one went in support of objects which were not only useless but detrimental to the purposes of medical research. By the rejection of the Bill Parliament would show its appreciation of the efforts that had been made by scientific men through these researches to prevent and cure diseases, and it would be an argument in favour of research generally. The Bill itself was very inconclusive and contradictory.

Sir F. BANBURY said that the mover of the amendment seemed to have forgotten that a great change had been made in the Bill since it obtained its second reading. All that it did now was to require that a special certificate must be secured in the event of a dog being used for certain experiments. The amendment by which the form of the Bill was changed on the report stage was recommended to the House by a Member of the Government on the ground that the Government wished to make the measure accord with the recommendations of the Royal Commission, and all that the Bill now did was to say that a certificate must be required. Now they had the Government represented by another Minister sending out a three-line whip in order to cancel and render nugatory the amendment which they had themselves put into the Bill a short time ago.

HON. MEMBERS: And quite right, too!

Sir F. BANBURY said it was a breach of faith with the House. (Cries of "No, no" and "Nonsense.")

Sir H. CRAIK said he did not consider the attitude of the Government as inconsistent. He asked if it was suggested that men had no right to use animals for human advantage. If a shred of danger to human life was involved, would anyone in order to seek aid for a child of his own or anyone else's not even ride a horse to the death?

#### *The Bill Contrary to the National Well-being.*

Dr. ADDISON (Minister of Health) said he refused to bow under the reproach poured upon the Government and argued that there was nothing inconsistent in their attitude. They

had come to the conclusion that notwithstanding the amendment inserted on the report stage they would still advise the House to reject the Bill. There was no inconsistency in that procedure. The Bill, as it stood, would permit a number of experiments on dogs. Sir F. Banbury said it was only a question of a certain certificate being required. That was just it; it was something they had to do in addition to what they had to do now. Already a licence must be held for an experiment upon an animal, and the experiment must be performed in a licensed place; the animal must be fully anaesthetised, and must remain under the anaesthetic without recovery unless another certificate was obtained to permit the animal to recover, as was sometimes desirable when experiments in feeding were being made. A further condition in regard to dogs and cats was that an additional certificate was required that either a dog or a cat were necessary on which to make the experiment. By the Bill it was proposed to add to all these conditions and qualifications the requirement of a further certificate that the object of the experiment would necessarily be frustrated unless it were performed on a dog, and that no other animal was available for such experiment. That was a considerable thing to ask in addition to all the other requirements. The practical question was, were they justified in imposing that further restriction on people who were already very strictly restricted, especially in the case of dogs? He had not heard a case brought forward in which there had been an abuse of the existing procedure, or in which it had been shown that the present very exacting scheme of restrictions had been found to be insufficient. There seemed to him no reason for putting a further restriction on research. Dogs had been used in the research in connexion with poison gas because with them it could be seen, as it could not be seen with horses or mules, for example, whether the protection was reasonable or not; and the finest mask which was on the battle-field was elaborated. It would have been asking too much of the men who performed those experiments that they should need all the licences and certificates which he had enumerated. Then there were the series of painless experiments which were going on with relation to rickets in children, which some authorities believed to be due to the lack of a certain element of diet. Dogs could be kept in a laboratory and fed on a mixed diet at stated intervals, and they were being used for that purpose; but it would be unreasonable to require proof that the experiments would necessarily be frustrated unless they were performed upon dogs. These experiments were stated to be progressing, and it was to be hoped that they would be successful. It was still clear that as the Bill now stood it would make demonstration difficult and embarrassing, contrary to the best interests and well-being of the people. On that account, without any hesitation, any breach of faith, or any misgiving, he asked the House to reject the Bill on third reading.

After further discussion the House divided, when there voted—

For the third reading . . . . .	62
Against . . . . .	101

Majority against . . . . . 39

The Bill was accordingly rejected.

#### *Nurses' Registration Bill.*

The House considered the Nurses' Registration Bill as amended in Standing Committee.

An amendment was agreed to defining the term "registered children's nurse" as a children's nurse who was for the time being registered in the children's nurses' supplementary register.

Another amendment was also agreed to raising the membership of the Council from 42 to 45 members.

Lieutenant-Commander ASTBURY moved to leave out paragraphs (a) to (k) inclusive in Subsection (1) of Clause 4 relating to the constitution and appointment of the Council. The amendment was resisted by Dr. ADDISON in the name of the Government, and the debate upon it was adjourned.

MONDAY, JUNE 30TH.

#### *Local Government Board Vote.*

On a vote for £1,380,377 for the Local Government Board, Dr. ADDISON (Minister of Health) said that this Vote would in future be incorporated in the Vote for the Ministry of Health. In connexion with demobilisation, one of the earliest fears that had been entertained—which had been justified to some extent by the event—was that so many men serving overseas in countries where they were likely to be infected with tropical diseases of various kinds might mean the spread of the diseases in this country. An interdepartmental organisation was accordingly set up to prevent the spread of such diseases, and, in the main, the methods which had been adopted had proved to be successful. In addition, a committee dealt with the subject of tuberculosis, which in many cases had been aggravated by hardships arising out of the war, and the

Board hoped to receive their recommendations in a short time. On June 1st the number of soldiers infected with the disease in institutions was 2000, and on the waiting list there were 364.

*The Work of the Medical Department of the L.G.B.*

The medical services of the Board, which now became merged in the Ministry of Health, were very diverse, but with respect to some of them they were only at the beginning. Up to the present they had had only 19 cases of small-pox, all of which had been arrested, and there were several cases of cholera, dysentery, and so on, which also had been prevented from spreading.

*Rabies.*—With regard to rabies, 54 cases had been notified, and six centres had been established in the country where anti-rabies vaccine could be obtained. The first 19 persons affected had to be sent to Paris, but subsequently 24 were treated in England, and 11 were afterwards treated with vaccine prepared in our own laboratories. It was rather a reflection upon us as a nation that we were dependent upon supplies obtained from our Allies in the early stages of the disease. None of the cases, he was glad to say, had developed into hydrophobia.

*Influenza.*—During the six months ended March 31st in England and Wales alone there were 136,000 deaths where influenza. That indicated the necessity for spending money in conducting research and inquiry into influenza, but at the present time he would not hold out any sanguine hopes of what they might be able to do in that direction. A great deal of inquiry was necessary before they could speak with any hopefulness on that subject.

*Veneral diseases* was another topic on which he ought to say a word. They had a number of critics of the action they had taken. Under the Regulations issued in July, 1916, 75 per cent. of the cost of schemes designed to conquer venereal diseases was paid by the State. There were at the present time 146 centres, of which some were exceedingly good. A large number of those centres were not, in his opinion, doing as well as they would do in time, and they needed not only 140 but 1000 centres at the very least. The difficulty was to obtain the staff with the modern training arising out of the experiences of the war to carry them on. It would only be gradually, and they would develop and train the personnel and organisation throughout the whole country to make the best use of these centres. The Board had sometimes been blamed because they did not support compulsory notification. His view—and he thought the Committee would support him—was that it was quite hopeless to require compulsory notification until they had completely or substantially completely organised throughout the country efficient and up-to-date methods of treatment, otherwise they would drive people wholesale into various imperfect methods and very largely into the arms of quacks. One very important matter that they had got to work out in detail was to try to get the centre conducted on such lines that the people needing its assistance would readily go to it. The numbers in attendance in 1917 were 205,000; in 1918 they were 488,000.

*Tuberculosis.*—With regard to tuberculosis, although they had increased the number of beds available by 1500 during the past year, their methods were far from being sufficient, and it was quite useless to expect that they would be able successfully to cope with the disease until they had got an improved state of national housing. They had at present before them proposals for 3300 additional beds. The grants made last year were £383,000.

*Maternity and child welfare centres* was another branch of their work which they would have to develop, and this went hand in hand with improved nursing and midwifery services. All these services were to a great extent in an experimental stage, and in all of them the limiting factor was the getting of the trained assistance necessary to do the work.

*The blind.*—The latest development of all was in connexion with the treatment of the blind. A Committee which had been working since 1917 with certain regional committees had made the fullest survey of the blind population of the country and had examined all the institutes where training was given. Just lately the Government had sanctioned the provision of £125,000 to be distributed in assisting the blind in their workshops, in homes and hostels, for home teaching, and for various miscellaneous services in institutions that had been carefully examined and approved.

Sir D. MACLEAN thought and Dr. Addison's statement was interesting but not satisfactory. It was shocking to hear that in six months the country had suffered the loss of 136,000 lives, many of them, no doubt, old people who could not pull their full weight in the national boat, but still the majority men and women in full activity. As the health of the community ought to be their first and most important care, he threw out the suggestion that the right honourable gentleman should make a statement on housing conditions and health matters at least once a month in order to stimulate local authorities and to spread knowledge as to the best way of meeting what in many cases were easily preventable diseases.

Lieutenant-Colonel RAW deplored the ravages caused by tuberculosis, and said that with the advent of the Ministry of Health he was certain that a much greater effort would be made to stamp out what was a preventable disease. There should be a much more generous system, and facilities should be provided free of charge at the national expense for treatment in the early stages of tuberculosis. Prevention was far better than cure. He suggested the advisability of a great educational campaign, the establishment of a national health institute, and the appointment of lecturers to instruct the public that this disease ought not to be in our midst. He went on to criticise the milk-supply of the country.—Lord H. CAVENDISH-BENTINCK complained that the Government was not doing all it should do to improve the very unsatisfactory treatment which was being accorded to discharged soldiers suffering from tuberculosis.

Major ASTOR (Parliamentary Secretary to the Local Government Board), replying to the debate, said that the Ministry of Health would embark on its official career with a real vision of what it hoped to do. He would not say that the number of institutions now available for the treatment of tuberculosis was adequate either in number or quality. But there was great difficulty in providing fresh institutions during the war. In 1914 the number of deaths from tuberculosis was 38,600 and in 1917 it was 43,100. These figures, however, must not be taken too rigidly. Allowance must be made for the fact that diagnosis was improving. Still there was no diminution. The disease was one which depended upon the social conditions of the people, and these had to be improved. Generally speaking, their policy was more and better accommodation and better treatment. He believed that the development of workshops and the provision of occupation would assist enormously. The lines they were going on were that it was far better to provide treatment for the population as a whole than merely to provide treatment for the tuberculous ex-soldier. The whole tendency was against specialising in particular diseases, but to make the local authorities and medical officers competent to deal with anything that might arise.

*The Welsh Board of Health.*

Brigadier-General Sir OWEN THOMAS asked the Secretary to the Local Government Board, as representing the National Health Insurance Commissioners, if the Welsh Insurance Commissioners had been appointed the Welsh Board of Health under the Ministry of Health; if so, whether he consulted the Members representing Wales before making the appointment; and whether he was aware that there was dissatisfaction in Wales with the manner in which the Commissioners discharged their duties as insurance commissioners.—Major ASTOR replied: The members of the Board of Health in Wales are appointed by the Minister of Health under Section 5 of the Ministry of Health Act, 1919; the three persons appointed as initial members have hitherto been members of the Welsh Insurance Commission, but the Board is not yet complete. The answer to the concluding part of the question is in the negative.

Sir O. THOMAS: Will the honourable gentleman make inquiries as to whether these three gentlemen have been on speaking terms for the last two years?—Major ASTOR: It would be very difficult to find out.

TUESDAY, JULY 1ST.

*Disabled Men and Compulsory Insurance.*

Colonel ASHLEY asked the Minister of Health whether, in view of the inequality of treatment meted out to totally disabled pensioners as compared with partially disabled pensioners in the matter of sickness and disablement benefits, men in receipt of disablement pensions amounting to over £26 per annum might be regarded as eligible for exemption from compulsory insurance or, alternatively, that no reduction of benefit should be made to a man drawing a total disablement pension if he was incapacitated from following his employment owing to causes unconnected with his pensionable disabilities.—Major ASTOR replied: A man in receipt of any disability pension exceeding £26 per annum is entitled to a certificate of exemption under the National Insurance Acts. It would not be feasible to carry out the suggestion contained in the last part of the question owing to the difficulty in practice of differentiating between incapacity resulting from the original disability and incapacity resulting from other causes. But the 1917 Act provides for the resumption of the right to full sickness benefit in the case of any total disability pensioner who has, in fact, re-established his working capacity.

LITERARY INTELLIGENCE.—Mr. C. T. Kingzett, F.I.C., the chairman of the "Sanitas" Company, Ltd., and one of the founders of the Institute of Chemistry, is preparing for early publication by Messrs. Baillière Tindall, and Cox (London), an abridged "Popular Chemical Dictionary" in a single volume.—Mr. Kimpton will supply a copy of an erratum slip for Macleod's Physiology and Biochemistry in Modern Medicine, recently published, to any reader who desires it.

## Appointments.

BANKS, CYRIL, M.B., B.S. Lond., D.P.H., has been appointed Medical Officer of Health of Stafford.  
 BREWER, W. K., M.R.C.S., L.R.C.P. Lond., Honorary Anaesthetist to the National Dental Hospital, Great Portland-street.  
 GRAY, H. T., F.R.C.S., Honorary Surgeon to the Infants Hospital, Vincent-square, Westminster.  
 TIBBLES, SYDNEY, L.R.C.P. & S. Edin., Honorary Ophthalmic Surgeon to Western General Dispensary.  
 Royal West Sussex Hospital, Chichester.—H. E. RUTHERFORD, M.D., B.Ch., B.A.O. Dub., Honorary Physician; HAMILTON, G., M.B., B.S. Lond., Honorary Assistant Surgeon; and EUSTACE, G. W., M.D. Dub., Honorary Radiographer.  
 St. Thomas's Hospital.—BIRLEY, J. L., M.D., B.Ch. Oxon., and TIDY, H. L., M.D., Ch.B. Oxon., Physicians in charge of Out-patients; PAGE, C. M., M.B., M.S. Lond., and ROMANIS, W. H. C., M.B., M.C. Cantab., Surgeons in charge of Out-patients; JEWESBURY, R. C., M.D. Oxon., Physician in charge of the Children's Department; WYATT, J., M.B., B.S. Lond., Obstetric Physician in charge of Out-patients; JONES, SIR ROBERT, K.B.E., Director of the Orthopaedic Department; and WORDLEY, E., M.B., B.C. Cantab., Medical Registrar.

## Vacancies.

For further information refer to the advertisement columns.

Ashlon under Lyne, Lake Hospital.—Res. Asst. M.O. £300.  
 Barnsley, Beckwith Hospital.—H.S.  
 Belgrave Hospital for Children, Clapham-road, S.W.—Asst. P. Also Asst. S.  
 Bezel, Kent, London County Mental Hospital.—Asst. M.O. 7 gns a week.  
 Birkenhead Borough Hospital.—Hon. Dentist.  
 Birmingham General Hospital.—Res. M.O. £155.  
 Birmingham, St. Chod's Hospital, Edgbaston.—Res. M.O. £150.  
 Bradford City, Odal Sanatorium.—Res. Asst. M.O. £300.  
 Bristol, Cosham Memorial Hospital, Kingswood.—Res. M.O. £200.  
 Cape Town University, South Africa.—Profs. of Med., Surg., Obstet. and Gynec. £1250 each.  
 Carmarthen Mental Hospital.—Second Asst. M.O. £250.  
 Chelsea Hospital for Women, Arthur-street, S.W.—H.S. £120. Also Registrar. £50.  
 Chorley Borough Education Committee.—Asst. Sch. M.O. £400.  
 Devonport, Royal Albert Hospital.—Res. H.S. £200.  
 Edinbane, Isle of Skye, Gesto Hospital.—Res. M.O. £300.  
 Evelina Hospital for Children, Southwark, S.E.—Hon. P. and S. to Out-patients. Also Hon. Dental S. Also H.P. £160.  
 Glasgow Education Authority.—Asst. M.O. £400.  
 Great Northern Central Hospital, Holloway, N.—H.S. £150.  
 Greenwich Metropolitan Borough.—Female M.O. for Maternity and Child Welfare Work. £400.  
 Greenwich Union Infirmary, Vanbrugh Hill, East Greenwich, S.E.—Dep. Med. Supt. and Asst. Med. Supt. £400 and £300 respectively.  
 Hong Kong.—Bact. and Path. £600.  
 Hospital for Consumption and Diseases of the Chest, Brompton.—H.P. Hospital in Serbia.—Surgeon.  
 Hospital for Sick Children, Great Ormond-street, London, W.C.—P. and S. Also Surgical Registrar. £200. Also H.S. £50.  
 Huddersfield County Borough, Bradley Wood Sanatorium. Res. M.O. Hull, City and County of Kingston-upon-Hull Infectious Diseases Hospitals.—Res. M.O. £450.  
 Italian Hospital, Queen-square, London, W.C.—Hon. Asst. S.  
 London (Royal Free Hospital) School of Medicine for Women.—Two Demstrs. of Anat. £250. Also Female Pharm. £250.  
 London Temperance Hospital, Hampstead-road, N.W.—Cas. O. £120.  
 Loughborough and District General Hospital and Dispensary.—Res. H.S. £250.  
 Liverpool, Bootle Hospital, Derby-road.—Hon. Ophth. Surg. and Hon. Dent. Surg.  
 Maidstone, West Kent General Hospital.—H.S. and Asst. H.S. £250 and £125.  
 Manchester Children's Hospital, Gartside-street.—Asst. M.O. £200.  
 Manchester Children's Hospital, Pendlebury, near Manchester.—Res. M.O.'s £150.  
 Manchester City.—M.O. £450.  
 Manchester Ear Hospital, Grosvenor-square, All Saints—H.S.  
 Manchester, St. Mary's Hospitals for Women and Children.—Two H.S.'s £100.  
 Merthyr Tydfil County Borough.—Female M.O. for Maternity and Infant Welfare Work. £500.  
 Mile End Infirmary, Bouverie-road, E.—First Asst. M.O., Second Asst. M.O. £300 and £250.  
 Miller General Hospital for South East London, Greenwich-road, S.E.—Hon. Asst. Gynec.  
 Otago University, New Zealand.—Prof. of Syst. Med., Prof. of Clin. Med. and Therap., and Lect. on Clin. Med. £600, £500, and £400 respectively.  
 Plymouth, South Devon and East Cornwall Hospital.—H.P. £140.  
 Port Sunlight Cottage Hospital.—Res. M.O. £250.  
 Prince of Wales's General Hospital, Tottenham, N.—Hon. Asst. P., Hon. Med. Regist., and Hon. Anaesth. Also Clin. Assists.  
 Queen Charlotte's Lying-in Hospital, Marylebone-road, N.W.—Phys. to Out-patients.  
 Queen Mary's Hospital for the East End, Stratford, E.—Two Asst. Hon. P.'s.  
 Rhondda Urban District Council.—Asst. Sch. M.O.'s and M.O.H.'s. £500. Also Two Dent. Surgeons. £400.  
 Royal Chest Hospital, City-road, E.C.—Asst. P.  
 Royal London Ophthalmic Hospital, City-road, E.C.—Curator and Librarian. £120.  
 St. Bartholomew's Hospital.—Asst. Administ. of Anaesth.  
 St. Helen's Education Committee.—Dentist. £400.  
 St. Mary's Hospital for Women and Children, Plaistow, E.—P. to In-patients and Out-patients, P. to Skin Out-patients, Dental S.

St. Peter's Hospital, Henrietta-street, Covent Garden, W.C.—Anaesth. £25.  
 Salford County Borough Education Committee.—Asst. School M.O. £400 to £600.  
 Salford Royal Hospital.—Three Anaesths. £50.  
 Sheffield Royal Infirmary.—Asst. H.P. £150. Oph. H.S. £150.  
 Southampton County Borough Isolation Hospital.—Res. M.O. £400.  
 Southern Rhodesia.—District S.'s. £375 to £500.  
 University College Hospital, Gower-street, W.C.—Clin. Asst.  
 Wakefield General Hospital.—Jun. H.S. £150.  
 Wigan Infirmary.—Jun. H.S. £225.  
 Willesden Urban District Council.—Locum Tenens Asst. M.O. 10 gns. p.w.  
 Winchester, Park Prewett Asylum.—Med. Supt. £1000.  
 Winchester, Royal Hampshire County Hospital.—Obstet. P.  
 Wolverhampton and Staffordshire General Hospital.—Path. & Bac. £350.  
 Also Res. M.O. £200.  
 Workop, Victoria Hospital and Dispensary.—H.S. and M.O. £250 to £300.  
 York Dispensary.—Res. M.O. £250.

## Births, Marriages, and Deaths.

### BIRTHS.

BLAKEWAY.—On June 29th, at The Cottage, Poplar-grove, Woking, the wife of the late Harry Blakeway, M.S., F.R.C.S., B.Sc., of a daughter.  
 COLLINS.—On June 26th, at the White House, Yoxford, Suffolk, the wife of Dr. E. A. Collins, of a son.  
 WINDER.—On June 23rd, at Upper Fitzwilliam-street, Dublin, the wife of Captain A. S. M. Winder, R.A.M.C., of a daughter.

### MARRIAGES.

HOWE—BARRETT.—On June 24th, at St. Barnabas Church, Woodside Park, George Hubert Howe, L.D.S. R.C.S. Eng., to Kathleen, elder daughter of the late Mr. S. G. Barrett, of Liskeard, Cornwall, and of Mrs. Jenking, Plymouth.  
 PHILLIPS—SMITH.—On July 2nd, 1919, at All Saints' Parish Church, Bradford, by the Rev. A. F. Alston, James Phillips, F.R.C.S.E., Major, R.A.M.C., to Rose Agnes Smith, daughter of Mr. David Smith, of Windsor-road, Southport.  
 SILLARS—OGILVY.—On June 26th, at the Parish Church of Clova, Kirriemuir, Joseph Sillars, M.B., C.M., Kirriemuir, to Margaret Elizabeth, youngest daughter of the late Mr. David Ogilvy and Mrs. Ogilvy, Rottal, Clova.  
 SMITH—DRUMMOND.—On June 28th, at St. Augustine's, Queen's Gate, Captain Charles Rees Smith, R.A.M.C., to Helen Fidena, youngest daughter of the late John Drummond, Esq., of Sevenoaks, and Mrs. Drummond, Manson-place, Queen's Gate, S.W.  
 WILLIAMS—DURANT.—On June 26th, at Highbury Chapel, Bristol, Captain Geoffrey Comeline Williams, R.A.M.C. (T.F.), to Irene Mary, daughter of the Rev. W. F. and Mrs. Durant, of Woodland-road, Tyndall's Park, Bristol.

### DEATHS.

CARTWRIGHT.—On June 23rd, at Oswestry, John Peplow Cartwright, M.R.C.S. Eng., aged 70.  
 FEARSIDES.—On June 28th, as the result of a boating accident, Edwin Greaves Fearnside, M.D., F.R.C.P., Assistant Physician at the Hospital for Epilepsy and Paralysis, Maida Vale, late Major, R.A.F. Medical Service.  
 MCCALL.—On June 27th, of pneumonia, at a nursing home, Sir John McCall, K.C.M.G., M.D., LL.D., Agent-General for Tasmania, aged 58.  
 PUREFOY.—On June 27th, at his residence, Merriem-square, Dublin, E. Dancer Purefoy, LL.D., M.D., F.R.C.S.I., late Master of the Retunda Hospital, Dublin.  
 SAVERY.—On June 25th, 1919, at Budleigh Salterton, Devon, Dr. W. H. Savery.  
 SIMPSON.—On June 27th, at Scroope-terrace, Cambridge, Captain James Christian Simpson, R.A.M.C. (T.), M.D. Edin.  
 N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

### BOOKS, ETC., RECEIVED.

BALE, JOHN, SONS, AND DANIELSSON, London.  
 Barbed Wire Disease: A Psychological Study of the Prisoner of War. By A. L. Vischer, M.D. Translated from the German with additions by the Author. With Introduction by S. A. Kinnier Wilson, M.D. Pp. 84. 3s. 6d.  
 CHURCHILL, J. AND A., London.  
 First Lines in Dispensing. By E. W. Lucas, F.I.C., and H. B. Stevens, F.I.C. 2nd ed. Pp. 182. 6s.  
 HEFFER, W., AND SONS, London.  
 Practical Physiological Chemistry. By S. W. Cole, M.A. 5th ed. With Introduction by Professor F. G. Hopkins. Pp. 401. 15s.  
 HEINEMANN, WILLIAM, London.  
 Anaesthesia and the Nurse's Duties. By A. de Prenderville. With Introduction by Sir James Cantlie, K.B.E. Pp. 100. 3s. 6d.  
 Anaphylaxis and Anti-Anaphylaxis and their Experimental Foundations. By Dr. A. Besredka and Dr. E. Roux. English edition by S. Roodhouse Gloyne, M.D. Pp. 143. 6s.  
 KEGAN PAUL, TRENCH, TRUBNER AND CO., London.  
 Geriatrics: The Diseases of Old Age and their Treatment. By I. L. Nascher, M.D. 2nd ed. Pp. 527. 21s.  
 Rest, Suggestion, and other Therapeutic Measures in Nervous and Mental Diseases. By F. N. Dercum, M.D. 2nd ed. Pp. 335. 21s.  
 MACMILLAN AND CO., London.  
 On Longevity and Means for the Prolongation of Life. By Sir Hermann Weber, M.D., F.R.C.P. 5th ed. Pp. 292. 12s. net.  
 MURRAY, JOHN, London.  
 Heredity. By Professor J. Arthur Thomson. 3rd ed. Pp. 627. 15s.  
 THE NILE MISSION PRESS, Cairo.  
 The Surgery of Egypt. By F. C. Madden, M.D. Pp. 394.

# Medical Diary for the ensuing Week.

## SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

### MEETINGS OF SECTIONS.

Wednesday, July 9th.

NEUROLOGY (Hon. Secretary—C. M. Hinds Howell): at 8.30 P.M.

Paper: Colonel E. Farquhar Buzzard: Encephalitis Lethargica and its Results.

Colonel Buzzard will also demonstrate Cases.

Friday, July 11th.

PSYCHIATRY (Hon. Secretaries—Bernard Hart, G. F. Barham): at 8.30 P.M.

Paper: Dr. C. G. Jung (of Zurich): The Problem of Psychogenesis in Mental Diseases.

### NOTICE.

The Society's house will be closed for cleaning during August.

The Royal Society of Medicine keeps open house for medical officers of all the Allied Forces, and invites them to make free use of its library and rooms. The Emergency Post Graduate Scheme, under the charge of the "Fellowship of Medicine," is also open to all medical officers. Particulars of this will be supplied by the Secretary. Fellowship of Medicine, 1, Wimpole-street, London, W.1.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c. HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY, July 9th.—4.30 P.M., Lecture:—Dr. Gosse: Rheumatic Myocarditis.

## Communications, Letters, &c., to the Editor have been received from—

- A.—Col. J. G. Adams, C.B.E., A.D.M.S.; Major A. Abrahams, O.B.E., R.A.M.C.; Dr. J. L. Aymard, Cape Town; Sir T. Clifford Allbutt, K.C.B., Cambridge.
- B.—Miss M. A. Broadhurst, Lond.; Dr. S. G. Billington, Lond.; Dr. J. Brown, Blackpool; British Science Guild, Lond.; Major P. Bahr, D.S.O., R.A.M.C.; Dr. J. F. Briscoe, Bournemouth; Col. R. J. Blackburn, C.B., C.M.G., C.I.E.
- C.—Dr. H. G. P. Castellain, Lond.; Major W. B. Cosens, R.A.M.C.; Dr. H. P. Cholmeley, Forest Row; Dr. F. G. Crookshank, Lond.; Dr. P. J. Cammidge, Lond.
- D.—Mr. H. Dickinson, Lond.; Dr. J. F. H. Dally, Lond.; Mr. G. W. Dorley-Brown, Lond.
- E.—Dr. S. Elias, Rotterdam; Mr. D. L. Eadie, Edinburgh; Col. T. R. Elliott, C.B.E., D.S.O., A.M.S., Lond.

Communications relating to editorial business should be addressed exclusively to the Editor of THE LANCET, 423, Strand, London, W.C.2.

THE Hampstead Medical War Committee announce that Lieutenant Colonel J. R. Whait, D.S.O., 124, Finchley-road, N.W.3; Major H. Meggitt, 180, Belsize-road, N.W.6; Captain W. S. George, 110, Finchley-road, N.W.3; Captain A. W. George, "Surrey House," Shootup Hill, N.W.2; Captain W. E. Hills, 25, Church-row, N.W.3; Captain H. C. Malleson, 30, Thurlow-road, N.W.3, are now demobilised and have returned to practice.

# Notes, Short Comments, and Answers to Correspondents.

## MEDICAL PIONEER AERONAUTS.

By F. JOHN POYNTON, M.D.

### The Airmen of the Eighteenth Century.

THE present seems to me an opportune time to give a few details, even though imperfect ones, of the part taken by our profession in the birth of aeronautics more than a century ago. We shall stray back to those fascinating times when brave pioneers, taking their lives in their hands, struggled to maintain the flickering life of this puling yet long-hopped-for infant, and we shall welcome with pride the men of our profession who helped to lead the way, Tytler and Jeffries, Sheldon and Sakaroff, among them. The reign of Louis XVI. was drawing to a close when his false brother, Egalité, the first royal aeronaut, was a witness of the classical ascents by de Rozier and d'Arlandes. How interesting, too, it is to recall that Garnerin, who first demonstrated to this country the use of the parachute, was aeronautical adviser to the great Napoleon. These early days were not wholly unscientific, for experiments were made with animals before de Rozier's first ascent in 1783, and I have in my possession an interesting little conversation in French dated 1783 and illustrated by a pencil sketch of the Montgolfier balloon with the conversationalists in the car. They were a cock, a duck, and a sheep, and their views on their elevated position are entertaining. A problem for the psycho-analyst is provided by the fact that the Comte d'Arlandes, who shared with de Rozier the glory of the first balloon ascent, was later broken for cowardice in the French army. The collector of medical pictures also will be interested in the first illustration of an injured aeronaut. This represents Arnold, who was pilloried in the *Gentleman's Magazine* in 1785, Vol. II., as "the Unsuccessful Aeronaut." He is seen with his balloon in one corner of the picture, dressed in the costume of the period, stumping on a wooden leg.

### The First British Aeronaut.

The first Briton to make an ascent in this island was "ballooning" or "enterprising" Tytler, who raised himself some 300 ft. from the Comeby Gardens, Edinburgh, on August 27th, 1784. He was a Scot born at Fearn, and was a strange and erratic genius whose fate should stir pity in us, if also, at the same time, some amusement. A poor man, the son of a Scotch minister, he earned a little money as a medical assistant on board a vessel plying to Greenland, with which he completed an honourable student's career at Edinburgh. He then made his first mistake, not unknown even in these days, by marrying a lady before he had means to support a family. He failed to establish himself in Edinburgh, and, always ahead of his times, tried next to conduct a laboratory at Newcastle. When that failed he started a chemist's shop at Leith. Meantime his wife left him and the children and retired to the Orkneys. Now Tytler had a literary turn with novel views on religion, and set to work to write some essays, which he printed on a printing machine of his own invention. This effort attracted attention and he commenced to establish a position for himself as a writer and editor. In 1776 he edited the second edition of the *Encyclopædia Britannica*, and apparently he was now on the up line to fortune. However, in 1783 the balloon epoch commenced, and he was badly bitten by the desire to become an aeronaut and took to the making of fire balloons. He snatched at great cost this one laurel leaf, the first ascent from the ground in this island. It was his only successful attempt, and from henceforth Tytler's career was once more downhill. Soon after he joined the cause of the "Friends of the People" and wrote a seditious article, for which he had to fly the country. After writing a treatise on surgery in Ireland he eventually went to America and died at Salem, away from all his relatives and friends.

### The First Cross-Channel Flight.

Jeffries was an American physician, but unfortunately at present I have not had the opportunity of discovering whether any biography is extant of his career, and would welcome any information on this point. He was the hero, with Blanchard, of the first crossing of the Channel, though he had previously ascended with the same aeronaut from the Rhedarium, near Grosvenor-square. The account of this Channel flight written by himself is a record of serene bravery, for an undertaking of this kind was a big thing in those days. Strong adverse winds had delayed the departure from Dover, and it was not until Jan. 7th, 1785, that the ascent was made on a still, bright, winter day. The aeronauts made very slow progress in their balloon,

for in 50 minutes they were only one-third of the way across the Channel! Trouble soon commenced and took a simple shape, the balloon insisting on descending into the sea. Ballast was heaved over, and then followed numerous pamphlets, which one would have thought from modern experience of such things would have lightened almost anything. For a while, indeed, there was an improvement but not for long, the precious instruments had to go, the balloon trappings, an empty bottle, their great coats, their lesser coats, their breeches, and so on. But what a man! He climbs up the netting and is enraptured at the lovely view he obtains as the balloon slowly revolves! Underneath a January sea is waiting for him, above is a winter sky, and around his immediate person a deficit of clothing! Fortunately for us all, just as they neared the French shore the balloon swept upward, cleared the cliffs, and carried them over the forest of Guines. Trouble was not over yet, but it was of a slightly different kind now, and the doctor's feelings must have been akin to those of the boy who eyes the volume and character of the birch that awaits him. It will be apparent that as the balloon was again rapidly falling, some importance was to be attached to the nature of the tops of the trees upon which they were landing. Jeffries thought they looked both high and hard, and he does incidentally admit that he and his colleague were cold. Now comes the acme of resource and as great a proof of bravery as ever the world can claim, he remembers that their bladders are full—for the weather was cold and the bottle they threw over was empty and the reflexes in those hardy old days were apparently impervious to fear. He estimated that thus they lightened the balloon by some 4 to 5 lb. and, glorious to tell, they landed softly on those trees and were soon warm and safe in the kindly hands of French hosts.

#### *A Professor in the Air.*

Sheldon has the credit of being the first Englishman to make a balloon ascent in England. This event was on Oct. 16th, 1784, although others have maintained that Sadler held this prize, ascending on the 12th from Oxford. There can be no doubt, however, that James Sadler was the first English aeronaut, for he made many successful journeys and had a great career as the first English aerial traveller. Sheldon at this time was professor of anatomy at the Royal Academy, and had been a pupil and assistant of William Hunter in Great Windmill-street. He subsequently became a surgeon to the Westminster Hospital and later to the Devon and Exeter Hospital. Blanchard took him under his wing and made his fourth ascent with him from Chelsea. One enthusiast described their trip as "the most extraordinary voyage ever performed by a sublunary being." Sheldon, too, was apparently satisfied, and returned to his anatomical and surgical studies somewhat humbled in scientific spirit, but not altogether sorry to be once more on the surface of the earth. It is of interest that in the second rapid ascent of the balloon Sheldon complained of pain in the ears.

#### *Remarkable Observations.*

Sakaroff was a Russian aurist who accompanied a very remarkable aeronaut, Robertson, in his Russian balloon ascents very early in 1800. Robertson was one of the few balloonists who made a real success of his job, for he died, we are informed, worth a million! He combined with courage enterprise and a bright imagination. He and his comrades were repeatedly making strange discoveries in the air. For example, one gentleman's head bulged so much that his hat would not fit, and on another occasion their voices became inaudible. One very interesting observation was, however, made by Robertson, that the electric spark is lengthened in the rarefied atmosphere, thus anticipating by many years the Geissler tubes. Sakaroff fades into shadow before his remarkable comrade, but doubtless he added to the early stock of knowledge upon ear troubles in aeronautics. These famous old heroes may make us smile over their difficulties, ambitions, and boasts, but it is with pride that one reads that our profession, apart from its purely scientific contributions to the subject, faced also the early practical dangers and brought us great honour.

#### COLONIAL HEALTH REPORTS.

*Leeward Islands.*—The total population of the colony at the last Census was 127,193. In the province of Antigua, with an estimated population of 31,782, the births in 1917 numbered 1076, being 33.86 per 1000, the percentage of legitimate and illegitimate births being 24.16 and 75.84 respectively. The death-rate was 29.89 per 1000, and the deaths of children under one year, exclusive of stillbirths, were 19.79 per cent. of the total. In St. Kitts the birth-rate was 34.909 per 1000, in Nevis 34.633, and in Anguilla 43.240, while the death-rate for St. Kitts was 29.245, for Nevis 21.207, and for Anguilla 14.767 per 1000. The illegitimate birth-rate for St. Kitts was 25.832 per 1000, for Nevis, 21.774, and for Anguilla 21.007, as against the legitimate birth-rate of 9.070, 12.908, and 22.254 for St. Kitts, Nevis, and Anguilla respectively. In Dominica the birth-rate was 30.65 and the

death-rate 28.18 per 1000; the illegitimate births exceeded the legitimate by 203. In Montserrat the birth-rate was 37.80 and the death-rate 16.21 per 1000. The general health was satisfactory. During 1917 6174 patients were admitted into the hospitals, and there were 340 deaths therein. The average number of inmates in the central lunatic asylum at Skerrets, Antigua, was 153. There are two leper asylums—one at Rat Island, Antigua, and the other at Port Charles in St. Kitts. The average daily number of inmates for the two institutions was 60 males and 48 females.

*British Honduras.*—The estimated mean population in 1917 was 42,732 (21,308 males and 21,424 females). The birth-rate was 40.275 and the death-rate 31.288 per 1000. Illegitimate births were 39.57 per cent. of the total. The health of the Colony during the year was remarkably good, and considerable progress was made in the campaign against the hook-worm disease, especially in the Orange Walk district.

*Sierra Leone.*—The number of European and American residents in 1917 was 1090, of whom 636 were military and 244 officials. The deaths of Europeans numbered 22, including 12 landed from vessels; nine officials were invalided during the year. The population of the Colony at the last Census was 51,572 (41,001 males and 34,571 females). The birth-rate in 1917 was 20 and the death-rate 24 per 1000; in Freetown the birth-rate was 23 and the death-rate 33 per 1000. The excess of deaths over births registered in the colony has been apparent in the returns for some years past and suggests that the population is on the decrease. There is, however, a constant influx into the peninsula of natives from the Protectorate, and the figures given must in any case be accepted with caution, as the present system of registration can hardly be described as effective. It is impossible to give any valuable account of the chief causes of death, as medical certification of death is neither compulsory nor usual. The population of the Protectorate at the Census of 1911 was estimated at 1,327,560, of whom 1,323,151 are natives other than those in military barracks, while the remainder, numbering 3426, are non-natives. In both the Colony and the Protectorate, but more especially in the latter, cases of small-pox made their appearance from time to time in 1917, but the infection was prevented from spreading into an epidemic. Thirteen public vaccinators were appointed, and out of a total of 105,988 vaccinations reported as performed 68,763 were returned as successful. The number of patients treated at hospitals and dispensaries throughout the Colony and Protectorate in 1917 was 51,765. At the Leper Asylum there were 4 patients at the beginning of the year and 4 were admitted; 2 died and 4 absconded. To the European Nursing Home there were 133 admissions during the year; of these, 62 were officials and 44 belonged to the mercantile and shipping communities.

*Strait Settlements.*—The estimated population of the Colony in 1917 was 809,869, the birth-rate was 30.65 per 1000, and the death-rate 36.98. The principal causes of death were malaria (3766 cases), infantile mortality (751), tuberculosis (3084), beri-beri (2075), and dysentery (1034). There were 176 deaths from small-pox, nine from cholera, and 44 from plague.

#### THE EUROPEAN CORN-BORER.

The appearance of the European corn-borer (*Pyrausta nubilalis*) in certain parts of the United States has led to the issue of an Order in Council prohibiting the importation of "all corn fodder or corn stalks, whether used for packing or otherwise, green sweet corn, roasting ears, corn in the cob, or corn cobs" from the affected areas into Canada. A circular dealing with this pest, said to be one of the most destructive that has ever reached America, has been issued by the Canadian Department of Agriculture, and can be obtained free from the Dominion entomologist at Ottawa.

#### LE CARNET DE POLITESSE.

The number of necessary "carnets"—or booklets entitling the owner to live, move, and have his being—has grown exceedingly in France, especially during the war, for, in spite of murmurings which are almost universal amongst his subjects, Monsieur Lebnean is still the reigning tyrant in French administration. That he should have captured the control of politeness among a people world-famous for the suavity of their manners is, indeed, a notable tribute to his stability and vigour. For many months there have been notices posted in tramcars and in the metro reminding passengers that they should give up their seats to the "mutilés"; now it seems that this has become a legal obligation. Every soldier who is blind or so wounded that standing becomes painful to him is entitled to a carnet, which gives him precedence in the seating accommodation. Even the phlegmatic Britisher needs no encouragement to make him offer his seat to a disabled fellow-countryman, and it is hard to believe that any wounded soldier, French or British, would stoop to enforce so obvious a right. The carnet de politesse is really an official aspersation on the nature of French politeness.

## The Goulstonian Lectures

ON

## THE SPREAD OF BACTERIAL INFECTION.

*Delivered before the Royal College of Physicians of London*BY W. W. C. TOPLEY, M.A., M.D. CANTAB., F.R.C.P.,  
DIRECTOR OF INSTITUTE OF PATHOLOGY, CHARING CROSS HOSPITAL.

## LECTURE II.

*(Continued from p. 5.)**B. Danysz INFECTIONS IN RODENTS.*

IN any attempt to obtain information on such points as these by experimental observation it is clearly necessary to work with some organism which is known to give rise to epidemic disease among the animals utilised. Such an organism is the bacillus isolated by Danysz, and the fact that the mouse is a susceptible animal is a distinct advantage in an inquiry of this type, where large numbers of animals must be employed.

Many observations have already been made on the effects produced by feeding cultures of this bacillus to small rodents, and some of the published reports contain data of considerable interest. This is especially true of the communication in which Danysz describes the original isolation of the bacillus, the difficulties which he met with in attempting to increase its virulence to such an extent as to make it practically useful in exterminating rats and mice, and the effects produced by the strain which he finally obtained.

The strain originally isolated, when fed to grey rats, produced a mortality of 20-30 per cent, some others becoming ill but eventually recovering, while the remainder were apparently unaffected. Many attempts were made to increase the virulence by passage. Whether this was carried out by feeding or by subcutaneous injection the final result was always a decrease instead of an increase in virulence, when the successively isolated strains were administered with the food. Sometimes there was a slight increase in virulence up to the second or third passage, but then it steadily decreased, and the final result was always the survival of all the animals fed on one of the later strains. For this reason it was very rarely possible to go beyond 10 or 12 passages. Passage obtained by allowing the animals of one experiment to eat the dead animals from the preceding one, so as to avoid the intermediate growth in artificial culture medium, led to exactly the same results. Passage carried out in collodion sacs placed in the peritoneal cavity again ended in greatly reducing the virulence as estimated by feeding.

*Explanation of Attenuation of Virulence.*

Danzs suggests as an explanation of this attenuation of the organism that it has to face different conditions in the alimentary canal and in the blood and tissues, and that increased virulence for the latter produced by successive subcutaneous injections, or in similar ways, results in lessened virulence for the former. He mentions in support of this view the fact that bacilli isolated from the blood or the spleen at the period when they are beginning to pass from the intestine into the tissues are more virulent, when fed to other animals, than organisms isolated after death—that is, after they have multiplied in the tissues for some considerable time.

He points out, further, that these results indicate that in epidemics caused by this bacillus the cessation of the epidemic will be due to the attenuation of the organism, as well as to the natural resistance of the rodents. An experiment is quoted in support of this.

Two mice, which had become ill after being fed on a culture of *B. Danysz*, were placed in a cage with 30 normal mice. At the same time another 30 normal mice were divided into six batches, all of which were fed on the same culture. All of these latter died in from four to six days. The first death occurred in the large cage three days after the death of the two sick mice. The epidemic lasted 23 days, at the end of which time there were three survivors. These, however, died a month later after being fed on a similar culture.

No 5002.

Danzs considers that this proves that they were neither completely refractory nor completely immunised, and that their survival during the epidemic could only be explained by the attenuation of the organism. Though this explanation is quite probable, it should be noted that feeding with large quantities of culture is hardly a fair test, since size of dose is probably an all-important factor, and a degree of immunity which might well have served to preserve the three survivors from the dangers of infection in the cage might prove ineffective against such a massive dose of bacilli.

*Production of Virulent Strains.*

Danzs then describes the method by which he ultimately succeeded in producing a strain of his bacillus possessing a markedly increased virulence for rats, and reports the results of various practical tests with regard to the possibility of destroying these animals on a considerable scale. Sometimes the method proved entirely successful; at others it seemed to have little effect. He calls attention to the importance of repeated exposure of infected food in the rat-infested locality at 10-12 day intervals, in view of the attenuation by natural passage referred to above.

It will be observed that in the above summary of Danysz's paper the term "virulence" has been employed in describing the power of the bacillus to produce death or disease on being fed to rodents. This is the term which he actually employs, but it obviously covers several different attributes.

The reports of subsequent observers have been mainly confined to the efficacy of the different forms of virus placed on the market as a means for destroying rats and mice. Mühlens, Dahm and Fürst, Liston, and Bainbridge have all carried out investigations on this point. There is a very general agreement among these observers that the various strains of bacilli employed show wide variations in the mortality which they produce when fed to rats under many different conditions. The question of the spread of the infection to rodents not fed with the virus does not appear to have been especially studied.

*EXPERIMENTS ON B. Danysz.*

In the following experiments an attempt has been made to investigate the changes which may occur in the pathogenicity and other biological characteristics of *B. Danysz* as the result of repeated passage by feeding, and to arrive at some conclusion as regards the propagation of the infection from sick to normal mice.

The culture which formed the starting point of these experiments was kindly supplied to me by Dr. Arkwright, of the Lister Institute. It was originally obtained from the Pasteur Institute in Paris, and was the strain investigated by Bainbridge in 1908-09. The general technique adopted was as follows:—

Small pieces of bread were soaked with a 24-hour broth culture of the strain to be examined, and these were fed to a varying number of mice, which had not been fed for 12 hours previously and were not fed again until next day. In general only one feeding was carried out in any one experiment, but in a few cases the mice were fed on two or three occasions within the first four days.

When a mouse was found dead a post-mortem examination was made, and small portions of the spleen and liver were transferred to broth with due precautions as regards sterility. On the following day plate cultures were made from the broth tube on McConkey's medium. After 24 hours' incubation the plates were examined and likely colonies were subcultured into litmus-lactose-peptone-water. The full fermentation reactions were subsequently examined and the organism was tested against a powerful agglutinating serum. At the same time an agar-slope culture was prepared, sealed up with paraffin wax and placed in the ice-chest. When a given organism was fully identified as *B. Danysz*, and it was desired to investigate its action on mice, a tube of broth was inoculated from the agar culture and incubated for 24 hours. The culture so obtained was fed to a fresh series of mice in the manner indicated above. Certain deviations were made from this routine in particular cases, but these will be indicated where necessary.

When the broth tubes to which the portions of spleen and liver had been added appeared sterile after 24 hours' incubation, and the plates inoculated from them showed no growth, they were incubated for at least 24 hours longer and fresh plate cultures made before they were discarded. It hardly ever happened, however, that where the first plate cultures remained sterile a growth was subsequently obtained, and broth tubes which appeared sterile after 48 hours' incubation invariably remained so.

*Some Difficulties Encountered.*

It is well to consider at the outset certain difficulties which have been encountered, and which seem inherent in an investigation of this kind. It is by no means easy to decide in many cases whether or no a mouse has died as the result of a *B. Danysz* infection.

In the first place, it is not always possible to make a post-mortem examination. An appreciable proportion of the dead mice are found partially or almost entirely eaten by their companions.

In the second place, the post-mortem findings are neither so typical nor so constant that great reliance can be placed upon them. The spleen is usually enlarged, often very considerably so. In a minority of cases the spleen and liver show multiple minute yellow areas. There is often an apparent enlargement of the lymphatic glands throughout the body, but this would seem to be a common feature in mice which have died from a variety of causes. The condition of the intestines varies enormously. In almost all cases it is the small intestine which shows variations from the normal. The most common condition in my experience has been a marked distension of this portion of the bowel with a bright yellow fluid. In other cases the lower part of the small intestine is plum-coloured, sometimes nearly black and apparently gangrenous.

A large number of sections have been examined from the organs of the mice dying during the course of these experiments, and similar specimens from other mice have been studied as controls. It has not been possible, however, to make out any constant changes which could be regarded as diagnostic of an infection with *B. Danysz*.

Another disturbing factor is the fact that a considerable proportion of the mice were found to be harbouring intestinal parasites in the shape of cestode worms. Dr. Leiper has

the earlier stages of the experiment, and partly in order that the survivors might be examined for any possible acquired immunity. In mice kept over such long periods it is inevitable that death should occur from causes other than infection with *B. Danysz*. Deaths which have occurred from ascertainable and extraneous causes have not been recorded. Thus mice which showed serious wounds as the result of fighting and died within a short time afterwards have not been included.

## RESULTS OF EXPERIMENTS.

Chart I. records the deaths of 197 mice which succumbed after being fed in the manner indicated. The black and shaded squares represent those animals from which *B. Danysz* was isolated post mortem. It will be seen that the majority of the deaths occurred within 30 days of feeding, and that, while *B. Danysz* was isolated from a high proportion of the mice dying during this period, it was seldom recovered from those dying at a later date. For this reason the records of each experiment are only given in the charts for the 30 days subsequent to that on which feeding was carried out, though in those few cases in which a late outbreak of disease occurred the fact is indicated in the text.

It is not possible to give full details of the various feedings, deaths, and post-mortem findings, but Chart II. indicates sufficiently the course of events during a series of such experiments lasting over about five months. The number of mice fed in each case is noted, and the deaths are recorded so as to show the time at which they occurred and the bacteriological results obtained.

Each experiment after the first was carried out by feeding a batch of mice on a culture of *B. Danysz* isolated from the liver or spleen of a mouse from a preceding experiment, the object in view being to ascertain whether any strains would be evolved showing striking variations as regards their patho-

CHART I.—Showing Time Relations of the Deaths of 197 Mice Fed on Various Strains of *B. Danysz*.

kindly given me the benefit of his great experience in this matter, and has examined some of the specimens obtained. He informs me that the degree of infection observed is not to be regarded as a heavy one, and gives it as his opinion that the only disturbing influence which the presence of these parasites might introduce into the general course of the experiments would be a certain degree of damage to the epithelium which might facilitate tissue invasion by the bacterial parasite.

Again, a mouse may die under circumstances which render it almost certain that it has succumbed to a *B. Danysz* infection, and pure cultures of this organism may be obtained from the spleen and liver, and yet the changes found post mortem may be practically negligible. Thus the bacteriological results seem to form our most certain criterion for diagnosis, but here, again, there are many difficulties to be faced. As pointed out above, a proportion of the dead mice are found partially eaten. In most cases the deaths were preceded by little or no evidence of illness, although there were exceptions to this. As a rule, one or more mice were found dead when the cages were examined in the morning. It would seem that post-mortem decomposition sets in very rapidly in these animals, and only a minority of the mice were in a condition which could be regarded as in any way ideal for bacteriological investigation. Although these facts must be borne in mind in drawing conclusions from the results obtained, yet the actual sequence of events, and the bacteriological results, leave little room for doubt as to the cause of death in the majority of cases. In most of the cases in which *B. Danysz* was isolated from the organs it was present in pure culture.

After a given batch of mice had been fed on a particular strain of the organism the animals were watched over a prolonged period, often several months. This was done partly to determine whether *B. Danysz* infections eventually develop in mice which show no evidence of illness during

genicity when subsequently fed to further series of mice. It will be observed that a proportion of the mice were killed while very ill, and these are recorded among the deaths. No mouse which became very ill was known to recover, and no error will be involved in this way. As pointed out above, most of the deaths have occurred in mice which showed no previous sign of illness, and definite symptoms have almost invariably been followed by death within 24 hours.

Preliminary feedings with the original strain showed little evidence of pathogenicity for mice, though subsequent re-testing at a much later date has credited it with more definite results. For this reason the original passage was carried out by feeding a small number of mice on the usual broth cultures on two occasions with an interval of one day between them, and then killing one of them with chloroform 24 hours after the second feeding. Cultures of *B. Danysz* were obtained from the liver and spleen, and that from the spleen was used in the next experiment. The survivors from this preliminary feeding showed no ill-effects during the considerable period for which they were kept under observation.

Examination of the chart reveals the fact that the strain from this first mouse showed definite pathogenicity on being fed to the 12 mice of Experiment 2. Eight of the 12 animals died, or were killed when dying, within 25 days, and from five of these cultures of *B. Danysz* were obtained post mortem. On the other hand, the deaths were unevenly distributed over the 25 days, and showed no tendency to be accumulated within a small time interval.

*Experiments 3, 3A, 3B, 3C, 3D, and 3E.*

Experiments 3, 3A, and 3B were carried out by feeding 12 mice in each case with a culture obtained from the spleen of a mouse which had been found dead during the course of Experiment 2. As will be seen, the strains employed in Experiment 3 and 3B were almost without effect.

In Experiment 3A six mice died within the first 24 days, but the first three of these were found almost entirely eaten, and in only one of the remaining three was

Key to Charts II. and III.

Each square represents an individual mouse fed on strain indicated.  
A, B, C, &c. = origin of strains used in subsequent experiments.  
= Mouse killed while apparently healthy 24 hours after feeding. *B. danyesz* isolated P.M.  
= Mouse survived more than 30 days.  
= Mouse found dead. *B. danyesz* isolated P.M.  
= Mouse killed while very ill. *B. danyesz* isolated P.M.  
= Mouse found dead or killed while very ill. No *B. danyesz* isolated P.M.  
= Mouse found dead or killed while very ill. Not examined P.M.  
\* On day indicated in left upper portion of square.

*B. Danysz* isolated post mortem. The deaths in this case were probably the result of the feeding, but the connexion is less definite than in Experiment 2, and the pathogenicity of the strain is less rather than greater. Thus in these three experiments, in which strains obtained from the spleens of mice found dead during the course of Experiment 2 were utilised, the effect of passage had been definitely to decrease the pathogenicity for mice when administered by the alimentary tract.

A strain of *B. Danysz* isolated from the spleen of a mouse of Experiment 2 which was found dying on the 25th day after the first feeding was fed to the 12 mice of Experiment 3C. The results showed no evidence of an increase in pathogenicity.

The strain isolated from the liver of the same mouse, the culture from whose spleen was employed in Experiment 3C, was fed to the 12 mice of Experiment 3D. This experiment gave results which seemed to point to a definite variation in the pathogenicity of the bacillus. Nothing whatever occurred during the first nine days following that on which the mice were fed, but on the 10th day one mouse was found dead, two mice dying, and several others obviously ill. One of these succumbed on the 14th day, but the others recovered. This forms the only instance in which several mice, which were obviously ill, recovered from the infection. The liver and spleen from the mouse which was found dead proved sterile. The two dying mice were killed, and cultures from the livers of both and from the spleen of one yielded pure growths of *B. Danysz*. The second spleen culture remained sterile.

The marked difference between the strains isolated from the liver and spleen of the same mouse of Experiment 2, which is indicated in this and in the preceding experiment, is worthy of notice.

The strain isolated from the spleen of the second of the two mice of Experiment 2, which died on the 25th day after feeding, was fed to the 12 mice of Experiment 3E. There was a considerable early mortality, five mice dying between the 4th and 7th day, but no bacteriological evidence was forthcoming that they had succumbed to a *B. Danysz* infection.

#### Experiments 4A and 4B.

By far the most definite evidence of pathogenicity had so far been afforded in Experiment 3D. The culture obtained from the spleen of one of the mice found dying on the 10th day of this experiment was fed to the 12 mice of Experiment 4A. The results were definite and striking. There was a period of 14 days during which nothing happened. Between the 15th and the 25th day, eight of the 12 mice died, or were killed in a dying condition. From the tissues of six of the eight mice *B. Danysz* was isolated post mortem. There could be no doubt here that a variant strain had been isolated showing a definite increase in pathogenicity.

A culture obtained from the liver of another mouse of Experiment 3D, which was found dying on the same day as the mouse which yielded the strain used in Experiment 4A, was fed to the 12 mice of Experiment 4B. The result was in sharp contrast to that obtained in the previous experiment, for there appeared to be an almost entire absence of pathogenicity.

#### Experiments 5A and 5B.

In Experiments 5A and 5B strains were employed from the spleens of two mice found dying on the 17th day of Experiment 4A. The results were curious and somewhat similar in the two cases. Both strains appeared to be almost devoid of immediate pathogenicity, but in each case a late outbreak of disease occurred. In Experiment 5A three mice succumbed on the 53rd day, and the six survivors were all found dead on the 74th day. From five of these last nine mice *B. Danysz* was isolated post mortem.

In Experiment 5B six mice died between the 56th and the 59th day; but since *B. Danysz* was in no case isolated, it is difficult to affirm that the deaths were due to infection with this organism, though the post-mortem appearances were entirely compatible with this being the case.

In what way these late deaths are related to the original feeding it is impossible to determine, but they can hardly be regarded in the same light as the deaths occurring within the first 30 days of the experiment.

#### Survey of Results: Further Experiments.

If we survey the results thus far obtained we see that as the result of passing the original strain of *B. Danysz* through a series of mice, the strain isolated from the tissues of one animal being fed to the animals of the next experiment, a strain has been evolved showing a definite increase in pathogenicity. In the next passage, however, this pathogenicity seems to have been lost or radically altered. It is clear, indeed, from the whole series of experiments that this loss readily occurs as the result of passage carried out in this way, and the original findings of Danysz are amply confirmed. That a definite increase in pathogenicity may also result has, however, been established. Another fact is quite definitely shown. Strains obtained from mice killed when very ill are much more likely to be pathogenic than strains from mice which have been found dead. Here, again, the results are in accord with those reported by Danysz.

In order to see whether a further increase in pathogenicity could be obtained, a fresh series was started, commencing with the strain isolated in Experiment 3D, which had been fed to the mice of Experiment 4A. The results are indicated in Chart III. The four mice of Experiment 4X were fed with this strain. All four succumbed on the 13th day of the experiment. One was found dead and partially eaten, the other three were dying. From each of these three *B. Danysz* was isolated post mortem.

Certain of the previous experiments had indicated that bacilli of varying pathogenicity might be isolated from the tissues of a single mouse. For this reason the broth culture from the spleen of one of the mice from Experiment 4X was fed to the mice of the next experiment without previous plating. A subculture made from it immediately beforehand gave a pure culture of *B. Danysz*. The spleen tissue itself was not fed to the mice.

The result of this experiment (5X) was striking. Twelve mice were fed. Two died on the 4th day, one on the 5th, and the remaining nine succumbed on the 11th day. From six of these nine mice *B. Danysz* was isolated.

In order to examine further the possible differences of strains of the bacillus isolated from the spleen of a single mouse the following procedure was now adopted.

A portion of the spleen from one of the mice which was found dying on the 11th day of the above experiment was rubbed over the surface of a plate of McConkey's medium, and then dropped into a tube of broth, which was incubated for 24 hours. At the end of this time a second McConkey plate was inoculated. From the scanty growth which developed on the first plate eight colonies were subcultured into broth and the tubes labelled A-H. From the second plate six colonies were picked off and the corresponding broth tubes numbered 1-6. All cultures were identified as *B. Danysz* by fermentation and agglutination tests.

Into each of seven cages were placed six mice. The first batch were fed on the broth culture obtained from the whole spleen (Exp. 6X). The next five batches were fed on cultures A-E obtained from colonies which developed on the plate inoculated directly with spleen tissue (Exps. 6X 1-6X5). The last two batches were fed on strains 1 and 3 obtained from colonies which developed on the plate inoculated from the original broth tube (Exps. 6X 6 and 6X7).

The chart shows the results. All the strains, with the possible exception of strain 1, showed definite pathogenicity. The broth culture obtained directly from the spleen tissue was no more pathogenic than the rest. Strain 3 stands out prominently, all the six mice of this experiment succumbing within three days. As *B. Danysz* was only isolated from one of the six mice, a second batch of the same number were fed on a broth culture obtained from the agar slope of this strain which had been placed in the ice-chest.

The result (Exp. 6X 8) entirely confirmed the high pathogenicity of the strain, all six mice were found dead on the 6th day, and from four of them *B. Danysz* was isolated post mortem.

From the strain isolated from the spleen of one of these mice six other mice were fed (Exp. 7X). The loss of pathogenicity is obvious, and we see again the tendency for successive passages to lead to the final loss by the parasite of the power of producing disease when administered with the food.

#### Experiments to Test Results of Prolonged Cultivation.

To exclude the possibility of the results noted being due to some extraneous factor rather than to variations in the biological properties of the bacillus, and to determine what

alteration, if any, would result from prolonged cultivation on artificial media, the strains which showed the widest variations were retested at subsequent dates. As mentioned above, the various strains isolated were grown on agar slopes, sealed with paraffin wax, and placed in the ice-chest. They were subsequently subcultured on to further agar slopes at intervals of six weeks, the fresh cultures, after 24 hours in the incubator, being preserved in the same way.

The original strain was tested on five batches of mice between July, 1918, and February, 1919. On the first occasion no mouse succumbed within 30 days. In the later experiments a few mice died in each case. The highest mortality occurred in the last test carried out, when four of eight mice died during the 30 days over which the experiment continued. From only one of these mice, however, was *B. Danysz* isolated. Moreover, the deaths, when they occurred, were irregularly distributed in time. On no occasion were more than one mouse found dead on any one day.

The strain from the spleen of the mouse of Experiment 3 D which was used in Experiment 4 A was retested on four subsequent occasions between September, 1918, and February, 1919. In the first experiment 8 of 12 mice died within 30 days, a mortality of 66 per cent. In the second experiment the mortality during the same period was 100 per cent. In the three subsequent tests the mortality was 66, 66, and 62 per cent. respectively. Moreover, there was a most definite time distribution. In each of the three earlier experiments there was an incubation period of 12 to 15 days, followed by an outbreak involving the death of a large proportion of the mice within a few days. The difference between the results of these experiments and those carried out with the original strain were most striking when actually observed. On the last two occasions on which this strain was tested the tendency to produce a series of deaths within a short time interval and following a definite incubation period seemed to have been lost.

Similarly, the strain labelled "Spleen 3 : 5 x : 9.12," which was employed in Experiment 6 x 7, was retested on three occasions within the following two months. It showed on the first three occasions a consistent tendency to produce a high and early mortality. Thus all the mice of the first experiment died within three days. All the mice of the second experiment succumbed on the 6th day. Four of six mice fed in the third experiment died on the 3rd day, while a fifth died on the 16th. On the last retesting this strain seemed to have lost its peculiar properties.

Two other strains which had shown particularly low pathogenicity were subsequently retested, and the results confirmed those originally obtained.

Thus two strains at least were evolved which possessed quite definite infective properties. One tended to produce an outbreak of disease after an incubation period of 12 to 15 days. The other led to the death of all the animals fed within a few days. These properties were maintained for weeks or months under artificial cultivation, but were gradually lost, and when finally tested the strains were indistinguishable from the original strain of *B. Danysz*.

No attempt was made to maintain the pathogenicity of the cultures by special methods of cultivation and storage. The exact combination of properties on which this pathogenicity depended was a subject for surmise, but it was clearly not simply a question of virulence in the strict conventional sense. It seemed better, therefore, to rely on the simplest methods of culture and observe any changes which occurred.

The results of observations on the factors possibly concerned in the loss of pathogenicity by passage, and especially on the question of the spread of the infection from the mice fed on cultures of the bacillus to their normal companions, will be considered in my last lecture.

ON

## STREPTOCOCCAL INFECTIONS OF SEPTIC WOUNDS AT A BASE HOSPITAL.

By ALEXANDER FLEMING, F.R.C.S. ENG.,  
HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND;

AND

A. B. PORTEOUS, M.B., B.S. LOND.,  
LATE PATHOLOGIST TO NO. 8 STATIONARY HOSPITAL, B.E.F., FRANCE.

IN connexion with streptococcus infections of wounds at base hospitals there are certain questions which are of fundamental importance.

*What are the Types of Streptococci that Require to be Seriously Considered in Wound Infections?*

There is one type of streptococcus which is predominant in septic wounds at the base. This type is responsible for almost all the severe septic complications of these wounds. It is to be found in pure culture in nearly all the infected joint cavities and fresh pockets of the wounds, and in our experience it has been responsible for all the streptococcal septicæmia following septic wounds.

**Characters of this streptococcus.**—It grows in broth in long chains of regular cocci. Some strains after 24 hours show very marked involution forms, the cocci being all shapes and sizes. The culture in broth consists of small woolly masses, which settle to the bottom of the tube (or along the side of the tube if it is incubated in a slanting position), leaving the upper portion of the medium clear. On agar (Douglas's tryptic agar) it grows well in moderate-sized colonies, which show by transmitted light a definite dark central portion, while the edges are slightly wavy and irregular. It does not liquefy gelatin. This streptococcus always grows better anaerobically, and not infrequently when first isolated it will not grow aerobically. After being cultivated for a short time, however, it grows freely under aerobic conditions. It is not constant in its sugar reactions. In the great majority of cases it ferments glucose, lactose, saccharose, and salicin, but not raffinose, mannite, or inulin. A few strains, however (about 12 per cent.), ferment mannite. These mannite-fermenting strains are identical morphologically with the non-mannite fermenters, and it has been shown by Douglas, Colebrook, and Fleming, in a report to the Medical Research Committee not yet published, by means of agglutination and absorption tests that serologically they are also identical.

**Clotting of milk.**—This test is very inconstant, and we have found that as regards the clotting of milk with these streptococci very much depends on the size of the tube in which the test is carried out. If the tube is of large size then the clotting is always delayed and it may even not take place in ten days, whereas in a small test-tube there is definite clotting in 24 hours. In a series of tubes of different sizes containing milk which had been heavily implanted with *Streptococcus pyogenes* and incubated for five days it was observed that no clotting had occurred in the two largest tubes, in the third tube clotting had occurred but there was no contraction of the clot, while in the smallest tube there was firm clotting with much contraction of the clot. This clotting of the milk in the smallest tube had occurred in the first 24 hours. Even in small tubes, however, the clotting of milk by *Streptococcus pyogenes* is quite inconstant and is worthless as a test.

**Hæmolytic power.**—All the strains of this streptococcus showed some hæmolytic power, but there seemed to be enormous differences in the amount of hæmolysin produced under the same conditions by streptococci which were isolated from the blood of septicæmic patients. In a number of cases the hæmolytic power was tested by centrifuging a broth culture and incubating for two hours at 37° C. dilutions of the clear supernatant fluid with washed human red corpuscles. In most cases, however, the question of whether these streptococci were hæmolytic or not was tested by noting the appearance produced by their growth on a blood agar plate (see Fig. 2).

**Incidence of this streptococcus.**—In a series of over 100 septic wounds (fractured femurs) which had remained at a base hospital for over seven days this streptococcus was present in almost every one. In cases of a similar nature where streptococci were recovered from the blood (47 cases) the organism was invariably of this type

*Is the "Hæmolytic" Character of the Streptococcus of Fundamental Importance—i.e., Can Non-hæmolytic Streptococci be Ignored for Practical Purposes in Wounds?*

As has been stated above, the only streptococcus which we have found to give rise to serious complications in a wound is the "pyogenes" type, which belongs to the hæmolytic group of streptococci, and we were forced to consider the non-hæmolytic streptococci to be of only secondary importance. In the more recent wounds, and especially in the wounds in which gas gangrene had developed, there is to be found very frequently streptococci of the "fæcalis" type. These are not present with anything like the same frequency in the latter cases. One of us (A. F.) in conjunction with Douglas and Colebrook<sup>1</sup> showed that streptococci (and other organisms) had a powerful effect in increasing the growth of anaerobic bacilli when grown with them in symbiosis. It may be that these streptococci of the "fæcalis" type have some importance in the wound on account of this symbiotic action, but alone they do not seem to be of any importance in wounds at the base.

*What is the Source of the Streptococci Found in Wounds?*

Examinations at a C.C.S. on recently inflicted wounds have shown that in only about 15 per cent. of cases is *Streptococcus pyogenes* present. Examinations at the base in cases which have been in more than a week reveal the presence of this organism in over 90 per cent. of the wounds.

During the summer of 1918 we examined a number of the gauze packs removed from wounds on arrival at the base. When the patient had been kept at the C.C.S. for more than three or four days *Streptococcus pyogenes* was present in almost every case. These cases correspond, therefore, closely with the patients who have been in base hospitals for more than a few days. Where, however, the patient had been sent straight on to the base after excision of the wound we found that *Streptococcus pyogenes* was present only in 15 out of 75 cases. Although in the majority of the packs from these recent cases we failed to find *Streptococcus pyogenes*, we were able to recover other microbes in every case from those portions of the packs which came from the depths of the wound, and often these microbes were present in very large numbers. The microbes isolated in these cases were chiefly anaerobic and aerobic bacilli and staphylococci.

It has been conclusively demonstrated that *Streptococcus pyogenes* will grow much better than these other microbes in the blood fluids<sup>2</sup> such as would be found in a recently excised wound, so that had the streptococcus been present as a primary infection it should have been demonstrable on arrival at the base. It is to be noted, therefore, that on arrival at the C.C.S. 15 per cent. of the men were infected with *Streptococcus pyogenes*; on arrival at the base (when the cases had been sent straight on after operation) 20 per cent. were infected, but after a stay at the base of a week over 90 per cent. were found to have *Streptococcus pyogenes* in their wounds. It would seem a warrantable deduction from these observations that the streptococcal infection of wounds is in most cases a hospital infection, and it is probable that in the dressing of the wound the infection is carried from one patient to another.

It has long been known that *B. pyocyaneus* is spread from one patient to another in a ward by faulty technique in dressing, as this infection is manifest to the naked eye by

the characteristic colour of the discharges. Other organisms which spread around a ward in the same way are *B. proteus* and diphtheroid bacilli. Now, as the *Streptococcus pyogenes* will grow in the discharges very much more readily than will these other organisms, it would be a miracle if it were not spread in the same way. It is unfortunate that infection by streptococci does not produce any characteristic change in the smell or colour of the discharges, as it does not obtrude itself on the notice of the surgeon until some serious complication arises.

*Have any Points Bearing on the Methods of Recovery from Streptococcus Infections Come to Light, and, if so, Can these be Exploited in Treatment?*

In cases of septicæmia following serious wounds the proportion of recoveries is very small. Out of a series of 40 cases of septicæmia following compound fracture of the femur we have seen only four recoveries. The reason for these recoveries is not very evident. All the patients who recovered were treated with streptococcus vaccine, but it was very difficult to demonstrate in any of these septicæmia cases any direct benefit from the vaccine.<sup>3</sup>

In some cases of pyæmia, however, and in many less severe cases, the administration of streptococcus vaccine in doses of 1,000,000 to 5,000,000 was repeatedly followed by a drop in the temperature and a feeling of well-being to the patient. It has often been demonstrated that, following the injection of streptococcus vaccine, there is a rise in the amount of antibodies in the blood. In cases of severe injury, such as a fractured femur, there are very often portions of the wound which are inefficiently drained and to which the blood fluids do not have access, and this militates against any very dramatic effect following the administration of vaccine in such cases. We hold a very strong opinion, however, that in all septic wounds where the surgeon secures good drainage no harm would be done and much good would result from a routine administration of stock streptococcus vaccine in doses of from 1,000,000 to 5,000,000 once a week. It is not practicable to make autogenous vaccines in every case, and it has been demonstrated by Douglas, Colebrook, and

Plate culture of 1 c.cm. of blood from a septicæmic patient taken immediately after being disturbed by being washed. Note the large number of streptococcus colonies and the zone of hæmolysis around each.

Fleming that when an animal is injected with one strain of *Streptococcus pyogenes* it develops antibodies (agglutinins) to the same degree to all strains. It would appear, therefore, that a stock vaccine would be as useful as an autogenous one.

In cases of septicæmia it seems much more likely that streptococci are being continually thrown into the blood stream from some septic focus than that they should actually be growing and multiplying in the blood stream. If they did flourish in the circulating blood, then they should be present in much larger number than they are. If 1 c.cm. of blood is taken from a septicæmic patient, mixed with liquid agar at 47° C., and plated, it is uncommon to get more than 100 colonies. Usually only two or three develop.

This method has been found to be the best for blood culture in such cases. In quite a large series of blood cultures it has never failed to reveal streptococci when they were found in fluid cultures, and in two cases streptococci were found when they failed to develop from blood added to

<sup>3</sup> It should be remembered, however, that in a large series of purpural septicæmia cases in which streptococci were demonstrated in the blood (Western (THE LANCET, 1912, i., 351) by the use of vaccines obtained a very high percentage of recoveries (45 as against about 10 in a control series not treated by vaccines). These purpural septicæmias do not seem to be very different from septicæmia following a septic wound.

<sup>1</sup> THE LANCET, 1917, i., 604.

<sup>2</sup> Wright: Proceedings of the Royal Society of Medicine, 1915.

broth or glucose broth. It has also the great merit that the number of streptococci in the circulating blood can be determined. The technique is as follows:—

1 c.cm. of blood from the suspected septicæmic case is added to about 5 c.cm. of water. The blood will thus be laked and the clotting power diminished, so that it can readily be carried back to the laboratory before coagulation takes place. It is then mixed with about 20 c.cm. of agar at 47° C., poured into a Petri dish, allowed to set, and incubated. In 24 hours the colonies can easily be seen.

Minced meat medium, such as is commonly used in the cultivation of anaerobes, furnishes a better fluid medium for blood culture in these surgical cases than does broth, glucose broth, or citrated broth. In several cases we have obtained growths of streptococcus from the blood in this medium when they failed to develop in the broth cultures. It has the advantage that anaerobes, if present, will also develop.

The figure represents a plate made from 1 c.cm. of blood from a patient with septicæmia following a flesh wound in the thigh. It shows very many more streptococci than are usually present in the blood. Two days after the specimen was taken the patient died, and the autopsy showed, in addition to a septic thigh wound, abscesses in the hand, wrist, both elbows, neck, and a very large abscess in the buttock. The specimen of blood was taken immediately the orderlies had finished washing the patient, during which process he must of necessity have been considerably disturbed, and it seems probable that the large number of streptococci in the blood was due rather to this disturbance than to their growth in the blood stream.

It is unlikely, also, that the small number of streptococci present in the blood stream in the ordinary case of septicæmia would be able to flourish in that situation, as the serum of these patients show by Sir Almroth Wright's sero-culture method a very much enhanced bactericidal power to *Streptococcus pyogenes*.<sup>4</sup> (The bactericidal power of normal serum to this microbe is practically nil.)

So far as we know, streptococci are destroyed in the body by three agencies: (1) bactericidal power of the serum; (2) direct bactericidal power of the leucocytes (without phagocytosis); (3) phagocytosis due to the combined action of the serum (opsonic power) and leucocytes. In streptococcal septicæmia these are changed from the normal as follows.

1. *Bactericidal power of the serum.* (This, as stated above, is increased.)

2. *Direct bactericidal power of the leucocytes.*—It has been shown<sup>5</sup> that living leucocytes have the power of destroying streptococci without ingesting them. This power of the leucocytes is apparently unaltered in septicæmia cases except that as there is always a leucocytosis in these cases the power is more manifest.

3. *Phagocytosis.*—In some cases of septicæmia the serum has lost completely or almost completely its opsonic power (and also its complementing power). The phagocytic power of the leucocytes is not diminished.

It would appear from these observations that, as a rule, it is not the circulating blood which is at fault in cases of streptococcal septicæmia, and in all probability we have to look for some deficiency in the local protective mechanism which allows access of the streptococci to the blood stream. It would seem to follow, also, that for the successful treatment of a case of septicæmia the most essential element would be the thorough local treatment of the infected focus.

It has been observed that when an infection has become circumscribed by the collection of leucocytes in the walls of the wound and by the other factors which operate locally in this connexion, it is very difficult to graft a serious streptococcal infection on the wound. It follows from this that the utmost care should be taken in the first few days after the injury to keep out the streptococcus and to avoid any treatment which will inhibit the defensive processes developing. In the after-treatment fresh tissue should only be opened up when there is a very urgent necessity.

In conclusion, we wish to express our thanks to Major M. Sinclair and our other surgical colleagues for permitting us to make observations on patients under their care; to Captain L. Colebrook for permission to use some of his experimental work; and to the Medical Research Committee for supplying us with apparatus which made the work easier.

## NOTE ON CERTAIN ORGANISMS ISOLATED FROM CASES OF INFLUENZA.

BY H. J. B. FRY, M.D. OXON.,  
CAPTAIN, R.A.M.C. (T.).

IN the course of investigation of material derived from cases of influenza during the three waves of the present epidemic, when searching for Pfeiffer's bacillus, Gram-negative, "Pfeiffer-like" bacilli were frequently isolated. They were not, however, hæmophilic, and grew rapidly and readily on ordinary agar. They have been isolated from sputum, post-mortem material, and in blood culture. The organisms derived from the latter source deserve further description.

They were isolated from the blood of two German prisoners, out of four cases examined, at the commencement of the third wave of the epidemic in February, 1919. The camp to which the prisoners had belonged had escaped the two previous waves, but was overwhelmed by the present one, a large proportion of the prisoners being severely attacked.

The organism was obtained in 2 per cent. glucose broth, and appeared in 24 hours in the blood culture, as round or oval Gram-negative "yeast-like" bodies, 3–5  $\mu$  long by 2–4  $\mu$  broad. Subculture to agar produced, not the above organisms but Gram-negative bacilli, varying in size from coccoid or coccobacillary forms to short filaments. The "yeast-like" bodies rapidly disappeared from the blood culture, and were replaced by clumps of Gram-negative bacilli, in the neighbourhood of which could be seen, in some cases, Gram-negative amorphous masses, resembling the ruptured envelopes of the above-mentioned "yeast-like" bodies.

### *Characters of Organism: Pathogenesis.*

The bacilli were pure in subculture, and had the following morphological and cultural characters:—

*Morphology and cultural characters.*—Small non-sporing bacilli, often grouped in parallel, or as diplo-bacilli, 1–2  $\mu$  in length, but varying in size from coccoid forms to short filaments. The smaller forms are actively, but the larger forms are feebly, motile. They are Gram-negative but not acid-fast. Polar staining is not usually present. They are aerobic and grow rapidly and well on agar, forming a whitish-grey moist growth of circular, slightly flattened colonies, about 0.5 mm. in diameter. Viewed by transmitted light, the colonies are translucent and slightly iridescent. In stab-culture on gelatin there is a white growth, confined to the needle track, without extension on the surface, and the gelatin is not liquefied. Broth is rendered turbid, with a flocculent, whitish, stringy deposit.

The fermentation reactions are as follows: Acid production but no gas in dextrose, maltose, and mannite. No change in lactose, cane-sugar, salicin, or inulin. Litmus milk is first rendered faintly acid and then becomes strongly alkaline, without any clotting. Neutral-red broth is rendered alkaline. There is a fairly well-marked indol reaction after 48 hours' growth in peptone water. Stalactite growth was not obtained in butter-fat broth.

Grown on 6 per cent. salt agar, numerous yeast-like forms were obtained resembling those obtained in the blood culture, together with filamentous, curved, and swollen forms. The organism resists heating to 65° C. for 30 minutes, but is killed at a temperature of 60° C. for 1 hour.

*Pathogenesis.*—The organism was highly pathogenic to the rat and guinea-pig. 0.25 c.cm. of a saline emulsion of a 24-hour agar culture by intrathoracic injection killed a white rat in 17 hours. The lesions produced were ecchymoses and hæmorrhagic extravasations on the surfaces of both lungs, which were congested and oedematous. The heart was engorged and filled with clot. The organism was recovered in pure culture from heart, lungs, and spleen.

A similar dose by intrathoracic injection killed a guinea-pig in five days, causing a slight caseous nodule at the site of inoculation, sero-purulent effusions into both pleural sacs, and lobular pneumonia with hæmorrhages in both lungs. The bronchial glands were greatly enlarged and showed caseous nodules. The heart was dilated and filled with clot. The organism was recovered in pure culture from the pleural effusion, lungs, heart blood, tracheal mucus, and spleen. By intraperitoneal inoculation death was caused

<sup>4</sup> For this observation we are indebted to Captain L. Colebrook.

<sup>5</sup> Wright, Fleming, and Colebrook, THE LANCET, 1913, i., 831.

in four days, with sero-fibrinous peritonitis and hæmorrhagic infarcted areas in the lungs.

The organism appears, therefore, to be related to the hæmorrhagic septicæmic group of bacilli, and in its cultural and fermentation reactions is somewhat similar to *B. pseudotuberculosis*. According to MacConkey,<sup>1</sup> the fermentation reactions of *B. pseudotuberculosis* and of *B. pestis* are practically identical. This is of interest in view of the general resemblance which exists between the pathological changes in the lungs in acute influenza and pneumonic plague. Moreover, forms resembling *B. pestis* were obtained in culture from the rat. Similar forms have been noted by Donaldson<sup>2</sup> in the sputum, and in the lung juice by Harris.<sup>3</sup>

One of the patients from whom this organism was isolated died, but the other recovered. The serum obtained from the blood of the latter in the third week after onset of the disease failed to agglutinate the bacillus recovered from his blood. Complement-deviation tests with the patient's serum and the organism as antigen appear to be positive, but require further investigation.

*Addendum.*—Since writing the foregoing statement a careful complement-deviation test with full technique, using Harrison's method, has been kindly carried out for me by Captain Lundie, R.A.M.C. An antigen prepared from the Gram-negative bacilli, together with the serum of the above-mentioned patient, gave complete deviation of complement in the following dilutions:—

	Complement: M.H.D. units.			
	1½	2½	3	5
Antigen control... ..	...	...	—	...
Patient's serum... ..	++	++	+	—

+ No hæmolysis. — Complete hæmolysis.

In view of the importance of the above observation, it was repeated with controls both for the serum and the antigen. The result was as follows:—

		Complement: M.H.D. units.		
		1	2	3
Controls	Antigen ... ..	—	—	—
	Patient's serum ... ..	+	Tr.	—
Test—Patient's serum... ..		+	+	+

Tr. Almost complete hæmolysis.

These observations therefore confirm the fact that in this case of "influenza" antibodies were developed in the patient's serum in response to the infection by the Gram-negative bacilli isolated from his blood.

It is of interest and some importance that experiments on the above lines with sera from cases of "influenza" obtained during the two preceding waves of the disease also show distinct deviation of complement with the above antigen. The results of these experiments will be published shortly. It would be valuable to carry out further observations with sera derived from recent cases of "influenza," if such are obtainable, since the above sera were naturally not fresh.

The organism, however, appears to bear some relation to "influenza" not only in its manifestation in the third wave of the epidemic, during which the organism was isolated, but to the two preceding waves. The presence of antibodies in the sera suggests the possibility of the preparation of an antiserum.

What relation, if any, this organism may bear to the filter-passing virus described by Bradford, Bashford, and Wilson<sup>4</sup> and other observers cannot here be considered, but an analogy may be noted in the epizootic pneumo-pleurisy of horses, with which the Gram-negative Pfeiffer-like *B. bipolaris equisepticus* is associated. In this disease horses have been infected with inflammatory mucus at a stage of its microscopical sterility.<sup>5</sup> *B. bipolaris equisepticus* belongs to the group of "pasteurella," to which also the organism above described may belong.

#### Another Organism.

In addition to the above Gram-negative bacillus another organism has been found in material derived from widely

different sources in cases of influenza. This organism has the following characters:—

*Morphology.*—Round or oval spores, 4–5μ in diameter, staining deeply with Gram in young cultures, but showing Gram-negative forms in older cultures. It is aerobic and grows well at 37° C. on ordinary media, especially those containing glucose. On serum-glucose-agar it forms thick, white, confluent growths. Individual colonies on agar are white, moist, circular and opaque, 1 mm. in diameter or upwards. In gelatin stab-cultures growth is confined to needle track, and there is no liquefaction of the medium. On media containing glucose there is produced a sweetish odour of fermentation. Dextrose and maltose are fermented, but not lactose, cane-sugar, mannite, salicin, or inulin. In milk there is no change, nor in neutral-red broth. The organism is not pathogenic to the rat by intraperitoneal or intrathoracic injection.

This organism has been found in cases of influenza in the sputum, urine, and even in the faeces of influenza patients affected with hæmorrhagic diarrhoea, and has been isolated from the sputum and from the lungs post mortem. The interest which attaches to this organism lies, however, in the forms which are derived from it in culture.

Grown in a sterile hanging-drop of glucose-broth, or in culture on serum-glucose-agar, a remarkable variety of organisms is produced. Not only are large hyphal threads obtained, varying in their reaction to Gram staining, even in the same thread, and containing Gram-positive spore-like bodies, but from the large spores or the hyphæ are derived by budding coccil forms. These are seen as clumps of cocci, or as oval or lanceolate diplococci, or in chains as diplo-streptococci or streptococci composed of elements with flattened opposed sides. These coccil forms vary greatly in the reaction to Gram staining, even in young cultures, so that in diplococci one element may be Gram-positive and the other Gram-negative, and similarly in the streptococcal chains.

Certain forms intermediate between the finer hyphal threads and the coccil chains are seen as pleomorphic bacilli in rosettes or clumps breaking down into coccil elements.

Mention may here be made that various forms resembling the above have been obtained in blood cultures from cases of influenza and in sterile catheter specimens of urine. In sputum, the large spores or their derivatives can be seen in cases of influenza, and their presence may be of value in diagnosis.

The organism thus derived from the large spore shows considerable resemblances to the "Organism D" described by Donaldson.<sup>2</sup> The streptococcal forms isolated by plating the growth obtained from the large spores in a hanging-drop of glucose-broth have, however, the following characters, which differ in some respects from "Organism D."

Short chains, usually not more than 8–12 elements, strongly Gram-positive in young cultures, but variable in the chain in older cultures. Elements of the chain composed more often of diplococci with flattened opposed sides than of lanceolate forms. Both types are, however, seen. Growth on agar is slight or absent, but on serum-glucose-agar or blood media minute streptococcal colonies are obtained, round, discrete, and raised. The colonies appear slightly granular by transmitted light. They do not hæmolyse blood media. A slight granular deposit is formed in broth. The fermentation reactions are acid in glucose, lactose, and maltose, no change in cane-sugar, mannite, salicin, or inulin. Milk is acidified without clot. The reactions, therefore, differ slightly from those of Donaldson's organism.

The streptococci thus obtained by plating, and the staphylococcal forms, are not pathogenic to guinea-pigs. The pleomorphic bacillary form is also non-pathogenic to the guinea-pig.

It is of interest to note that by prolonged growth (7 weeks) in a glucose-broth hanging-drop, very minute coccil forms are obtained, reaching the limit of the microscopical powers available. Crookshank has recently emphasised the possibility of a relation between filter-passers and non-filter-passers. It was noted in the Medical Review of the Foreign Press<sup>6</sup> that strangles has been transmitted by means of filtrates of infectious material, a disease associated with the *Streptococcus equi*, which resembles the pleomorphic organism of Rosenow.

It can be definitely stated, however, that the various forms described here are derived from the large oval spore and are stages in the growth of that organism. This suggests that influenza may be of mycotic origin. Further work is needed and is being carried out on the above organisms. A statement, however, of the results at present obtained seemed to be of value. I am indebted to Lieutenant-Colonel S. G. Butler, D.S.O., R.A.M.C., for facilities in connexion with this work.

## THE RESULTS TO BE EXPECTED FROM ANTENATAL CARE.<sup>1</sup>

BY EARDLEY HOLLAND, M.D. LOND., F.R.C.S. ENG.,

PHYSICIAN, CITY OF LONDON MATERNITY HOSPITAL; ASSISTANT  
OBSTETRIC PHYSICIAN, LONDON HOSPITAL.

I HAVE lately become convinced that both the medical profession and the lay public have been engaged in so impetuous a pursuit of antenatal work that they have not paused to consider what results they are really justified in expecting from it. What is the extent to which stillbirth and infant disease and mortality may be reduced by antenatal work?

Some, and they are the vast majority, expect too much. They believe that by something wonderful, almost magical, in treatment by drugs, diet, rest, and general hygienic measures almost every foetus doomed to death or disease may be made into a healthy infant. Others, who, I am glad to say, form a very small minority, are convinced that antenatal care will do positive harm by preserving the lives of those who would only become unfit and degenerate racial undesirables. It is easy enough to refute such a crude opinion as this, but the fact that it exists should make us all the more careful to be equipped with facts and figures in our advocacy of antenatal work.

### *The Need of Standardised Records.*

The time has come for us to make an assessment of our antenatal work; to balance our accounts and to find out what are our profits in relation to our capital outlay and expenditure. The amount of time, energy, and labour put into antenatal work at the present day is very great. Do the benefits gained therefrom represent a big, a moderate, or only an insignificant profit? We have got to find out whether our results justify our work. This paper has been written with that object, though the facts at present at my disposal do not allow me to do more than generalise. I hope to show that the present rate of foetal mortality is capable of being reduced by about one-half. But this end cannot be attained by antenatal methods alone; for not only are the majority of foetal deaths beyond the realm of antenatal care, since they are the direct result of the accidents and complications of labour, but antenatal care itself depends for its successful fulfilment on a high standard of midwifery. Without wishing for a moment to minimise the importance of the antenatal period, I desire to draw attention to the even greater importance of the intranatal period of foetal existence.

I should like to see records kept, on a standardised system, at every large maternity centre; this might well be insisted on by the State department which subsidises such centres. From the records of pregnancy, of labour, and of the year subsequent to labour, both for the mother and the infant, we should be able to state the profits of our enterprise. We should know how many foetuses were saved from probable death during pregnancy, how many from death or injury during labour; how many mothers were spared serious illness, or possible death, from the diseases of pregnancy and the injuries of labour.

The only records of pregnancy that have been published on these lines, so far as I am aware, have come from the pregnancy clinic of the Boston Lying-in Hospital. Dr. F. S.

Kellog considers what complications of pregnancy were found amongst 4996 cases. I will quote his own words:—

"Of these, 1524 showed some abnormality in pregnancy, 30 per cent.; albuminuria without other signs of toxæmia, 361, 7 per cent. of all cases, 23 per cent. of abnormal cases; elevated blood-pressure without other signs of toxæmia, 259 cases, 5 per cent. of all cases, 16 per cent. of abnormal cases; definite symptoms of toxæmia, 195 cases, 4 per cent. of all cases, 12 per cent. of abnormal cases; contracted pelvis of varying degree, 401, 8 per cent. of all cases, 26 per cent. of abnormal cases; heart lesions, 111 cases, 2 per cent. of all cases, 7 per cent. of abnormal cases; phthisis, 10 cases; antepartum hæmorrhage, 33 cases, which is 0.7 per cent. of all cases; pyelitis, 20 cases; syphilis 21 cases; gonorrhœa, 10 cases; chronic nephritis, 5 cases; diabetes, 3 cases; with occasional cases of fibroids in the lower segment, ovarian cysts, and other complications to the number of 30; also a large number of severe varicosities of the leg, and a small number of antepartum phlebitis. These figures establish the fact that pregnancy is not the normal physiological process it is so broadly considered, and that prenatal care is valuable in 30 per cent. of pregnancies that are in some degree abnormal; and that the only way to include this 30 per cent. is to give it to all; and that with 4 per cent. of all pregnancies showing definite toxæmic and pre-eclamptic symptoms, 2 per cent. of all pregnancies showing heart lesion, 8 per cent. of all pregnancies showing some degree of contracted pelvis, 0.7 per cent. of all pregnancies showing antepartum bleeding, to go no further, prenatal care is not only valuable, but is essential."

### *What is the Object of Antenatal Work?*

Antenatal work has for its aim the great economic principle of the prevention of waste. I am here dealing only with the foetus; the mother is another, a bigger, and—in my opinion—an even more important problem in relation to antenatal work. I will merely mention that maternal mortality and morbidity are enormously greater in cases of dead birth than of live birth. This is obvious, since the birth of a dead foetus is usually the consequence either of a pregnancy disease or of a severe labour, with the added risks of maternal injury or puerperal sepsis.

Quite apart from the waste of infants, it does not need a professional economist to appreciate the waste involved by the birth of a dead foetus. At the best there is a waste of time, a waste of energy, a waste of health, and a waste of money and material, distributed amongst the mother and family, the doctor, midwife and nurse, the National Health Insurance sickness and maternity benefits. At the worst there may be added to these permanent harm to the mother's health or even the loss of her life. The maternal mortality from childbirth is well enough known, but we have only a glimmering of the severe and slight illnesses that result from childbirth. We have not accurate figures for this, but they can and must be got. As some indication I have found that 40 per cent. of the patients who come to my gynaecological out-patients' department at the London Hospital come because of some post-parturient disease, usually only of a minor nature, but all the same it is enough to produce temporary, if not permanent, discomfort, or invalidism, or sterility. The only thing that can convert waste into gain; that can compensate for the discomfort, expense, and danger of child-birth, is the birth of a healthy infant. This is the object of antenatal care.

Let us consider what influence the reduction of foetal mortality is likely to have on the birth-rate. The desirability or otherwise of raising the birth-rate is a controversial point I will leave alone. The dead birth-rate for viable foetuses is about 3 per cent. Supposing we could by antenatal work reduce foetal mortality by one half, and thus cause an annual addition of about 12,000 infants to the population, would the birth-rate be thereby very much influenced? A birth-rate of 20 per 1000 would only be raised to 20.3. The reduction of the dead birth-rate by one half would be a most remarkable achievement, but it would only raise the live birth-rate by a fraction. If it is desirable to raise the live birth-rate there are quicker and more certain methods of doing so than antenatal care. There is a great deal of confused thought and loose writing about the tens of thousands of babies lost annually to the State from early abortion and dead-birth, excusable because it is good propaganda. The birth-rate is governed by profound economic factors beyond the influence of obstetrical science. If obstetrical science could bring it about that every conception reached healthy maturity the result would soon be a reduction in the number of conceptions.

<sup>1</sup> A paper read on July 1st at the National Conference on Infant Welfare organised by the National Association for the Prevention of Infant Mortality.

*Importance of Improved Intranatal Care.*

Leaving now the objects for which antenatal work strives, let us consider its results as regards foetal life. I intend to arrive at the answer to the question, "What really are the results to be expected from antenatal care?" by the consideration of two points: the distribution of the causes of foetal deaths amongst the 3 per cent. death-rate, and the preventive means at our disposal implied by the expression "antenatal care." We should thus be able to divide foetal death into two classes, (1) preventable and (2) not preventable, always with the sure hope that by scientific research, the class "preventable" may be constantly recruited from the class "not preventable."

Foetal death may occur during one of two periods: either during the long quiescent period of pregnancy, before the onset of labour—the antenatal period—or during the short stormy period of labour—the intranatal period. In the same way we must divide our preventive methods, our means for preserving the life and health of the foetus, into two distinct classes—antenatal methods and intranatal methods. By intranatal methods I mean the management of labour, normal or complicated. One of the chief points I wish to make is the immense importance in the prevention of foetal death of the management of the intranatal period. I do not hesitate to say that more foetuses can be saved by improved intranatal care than by antenatal care.

If a series of cases of dead birth be investigated the first great fact to become clear is that more foetuses are killed during labour from injury or accidental complications than die during pregnancy from foetal or maternal disease. A foetus that dies during the antenatal period is usually born in a state of maceration; one that dies during the intranatal period is in a fresh condition.

Out of every 100 dead-born viable foetuses you will generally find about 60 fresh and 40 macerated. Although the fresh foetuses will include a few that have died from antenatal causes shortly before the onset of labour, it is reasonably accurate to state that 60 per cent. of foetal mortality is due to the accidents and complications of labour. In other words, 60 per cent. are cases of intranatal death and 40 per cent. of antenatal death. This alone is an indication of the immense importance of improved intranatal methods for the reduction of foetal mortality.

*Relation of Antenatal to Intranatal Work.*

Another point which leads to the same conclusion is that antenatal work depends on a high standard of intranatal work for the fulfilment of its aims. Antenatal work is the strategy, intranatal work the tactics of preventive obstetrics. Consider for a moment the investigations we make at an antenatal clinic: (1) We measure the pelvis and estimate the relative sizes of the pelvis and foetal head, for we know the disasters of labour with a contracted pelvis; (2) we find out the presentation of the foetus, for we know that breech-labour has an appreciable foetal mortality; (3) we test the urine, for we know the consequences of untreated toxæmia of pregnancy; (4) we get the history of former pregnancies and labours, which often puts us on the track of syphilis; (5) we examine the pelvic cavity for obstructive tumours; (6) we investigate the general health of the mother, though we know that, with rare exceptions, the only unhealthy states of the mother, apart from the toxæmia of pregnancy, that cause foetal death are syphilis and renal disease. The list seems short enough, but its length is by no means commensurate with its great importance.

Now let us consider the treatment we adopt as the result of the above investigations. We find it is chiefly intranatal. The only purely antenatal treatment consists in the treatment of syphilis and in the treatment of the appropriate cases of toxæmia of pregnancy or of chronic renal disease by the simple means of diet, rest, and aperients. Otherwise we depend on the induction of premature labour, Cæsarean section, or on the careful management of labour with instrumental assistance when occasion demands.

*Causation of Foetal Death.*

I will now deal with the causes of foetal death and will try to indicate how many deaths are preventable, with special reference to the value of antenatal care in achieving this object. There is no need for me to enter in detail into these causes, for this part of the subject has already been dealt with by Dr. Amand Routh.

Taking first the macerated foetuses we can distribute them into the following groups: Syphilis, toxæmia of pregnancy, chronic renal disease, relative placental insufficiency from abnormal smallness of the placenta or excessive infarction, separation of the placenta by retroplacental hæmorrhages, and a great group in which the cause of death is undeterminable. Syphilis heads the list of deaths amongst macerated foetuses with 34 per cent., toxæmia of pregnancy comes next with about 20 per cent.; then comes the disappointing group with cause undetermined, about 20 per cent. We can place relative placental insufficiency and retroplacental hæmorrhage at about 18 per cent., and distribute the remainder amongst chronic renal and other maternal diseases and severe foetal deformities.

Turning now our attention to the fresh foetuses we shall find that in most of these death is due to the injuries and accidents of labour. There is a certain number due to the causes I have enumerated under the macerated foetuses, such as toxæmia of pregnancy or retroplacental hæmorrhage; cases in which the foetus died shortly before its birth and before it had had time to become macerated. Amongst these fresh foetuses we find that placenta prævia, accidental hæmorrhage, instrumental or natural delivery through a contracted pelvis, breech presentation, delivery by version, delayed labour from whatever cause, prolapse of the cord account for all but a very few. The most striking fact of all is that about one-half of these fresh dead-born foetuses show, on post-mortem examination, severe cerebral injury in the form of cerebral hæmorrhage and tearing of the septa of the dura mater; such injuries could only be caused by excessive cranial stress during labour.

*Consideration of Causes of Foetal Death in Regard to Prevention.*

I will now try to work out how many of these fatalities are preventable. It will be noticed that I have not attempted to give the ultimate causes of foetal death, but have only placed the cases in broad clinical groups. In giving the percentage frequency of each group I shall again only give approximate figures. This rough method is quite sufficient for the purpose, as I can only hope to indicate what can be done in a general, and not in a precise, way. For the purposes of preventive treatment we can conveniently place all cases of foetal death into four groups:—

1. Those, the cause of which can be discovered during the antenatal period and can be prevented by purely antenatal treatment. The great representative of this group is syphilis. Another example is toxæmia of pregnancy, many cases of which can be kept within reasonable bounds, or even cured, by simple antenatal treatment. Still another example is breech presentation, for which we can perform external version.

2. Those, the causes of which can be discovered during the antenatal period, but which depend for their prevention on intranatal methods. The best example of this is contracted pelvis. If discovered early enough in pregnancy the obstetrical treatment can be planned, and will be either waiting for natural labour, with the help of forceps if necessary, or induction of premature labour, or Cæsarean section. Another example is afforded by those cases of toxæmia of pregnancy which do not yield to antenatal treatment and which must be treated by induction of premature labour. Another rare example is obstructive pelvic tumours.

3. Those, the causes of which are not discoverable in the antenatal period, but which make their presence known just before or coincidently with the onset of labour, or during the course of labour. Examples of this group which are prolific of foetal death are the antepartum hæmorrhages. Other common ones are prolapse of the umbilical cord, cases of prolonged labour from such causes as persistent occipito-posterior presentations. In this group most of the foetuses have cerebral hæmorrhage and tearing of the septa of the dura mater, consequent on delivery by forceps or version.

4. Those, of which the causes, so far as our present state of knowledge stands, are not discoverable or preventable by any means whatever. These include the great group in which the cause of foetal death cannot be determined, the cases of relative placental insufficiency due to abnormal smallness of the placenta or to the destruction of a large area of placenta by infarction, those cases in which a blood-clot is found behind the placenta, and cases of severe foetal deformity such as anencephaly, hydrocephalus, and cedematous states of the foetus.

*The Respective Value of Preventive Methods.*

I will now attempt to make a rough estimate of how many foetal deaths are preventable and how many are not preventable, and will give a rough indication of the preventive part played by antenatal methods alone, by combined antenatal and intranatal methods, and by intranatal methods alone.

—	Incidence.	Preventable.	Antenatal.	Ante- and intranatal.	Intranatal.
Syphilis ... ..	15	15	15	...	...
Toxaemia of pregnancy ...	10	6	3	3	...
Complications of labour } (including antepartum } haemorrhage) ... ..	50	30	1	9	20
Chronic renal and other } maternal diseases ...	2	1	1	...	...
Cause undeterminable ...	12	0	...	...	...
Relative placental in- } sufficiency and retro- } placental clot ... ..	6	0	...	...	...
Foetal deformities ... ..	5	0	...	...	...
—	100	52	20	12	20

It is thus demonstrable that out of the 50 per cent. of foetal deaths which are theoretically preventable, about 20 per cent., of which three-quarters are syphilis, could be prevented by antenatal methods alone. We see that 12 per cent. depend for their prevention on combined antenatal and intranatal methods, and 20 per cent. on intranatal methods alone.

The point to which the foregoing line of reasoning has brought us is that although antenatal work is of immense importance, and we must not abate by one jot our enthusiasm for it, yet the importance of the intranatal period and the necessity of getting a better standard of midwifery must be recognised much more than it is at present. This conclusion is forced on us when we realise that the majority of dead foetuses have met their death in the intranatal period, that many cases of intranatal foetal death occur from causes beyond the control of antenatal care, and that antenatal care itself depends on intranatal skill for its successful issue.

In conclusion, I would appeal to this great National League, which has already done so much for maternity and child welfare, to use its influence in helping to bring about a higher standard of midwifery practice—an end which can only be attained through the better teaching of midwifery to medical students, midwives, and post-graduates alike, and by the establishment of enough maternity homes and hospitals to meet the needs of our population.

**PNEUMOKONIOSIS IN MAN AND HORSE.**

By W. C. RIVERS, M.R.C.S., D.P.H.,

TUBERCULOSIS OFFICER, BARNSELY DISTRICT, WEST RIDING, YORKS.

WHEN dealing with nasal defect and mouth-breathing<sup>1</sup> as contributory causes to pulmonary tuberculosis I brought forward among a priori arguments the fact that the Equidae, which breathe exclusively by the nose, very rarely suffer from tuberculosis (especially the pulmonary form), although no better housed than cattle, which are very subject to that disease and possess an air-way by the mouth. The thought occurred that it would be interesting in this connexion to test the comparative incidence of pneumokoniosis in man and horse working in dusty occupations, as in coal-mines. Accordingly, investigation and inquiry were begun.

*Views of Various Investigators.*

Veterinary authorities agree that pneumokoniosis is very rare in horses. Smith<sup>2</sup> says: "There is no such thing as miners' lung amongst them (coal-pit ponies), though many never come to the surface for years." Coal-dust is not mentioned amongst the causes of equine interstitial pneumonia in Friedberger and Fröhner's work.<sup>3</sup> It is put last in the list of such causes by Hoare,<sup>4</sup> and pneumokoniosis is

stated to be only an occasional form of equine chronic pneumonia.

Professor McQueen of the Royal Veterinary College, Camden Town, kindly informed me that miners' lung was very rare in pit ponies. He added that an unpublished post-mortem investigation of pit ponies' heads (in relation to possible penetration of the facial sinuses by the coal-dust) revealed that the dust was nearly all stopped at the nose. Messrs. R. C. Trigger and W. Trigger, F.R.C.V.S., who furnished the material, told me that, clinically, any lung disease is highly uncommon in pit ponies, who nearly all cease work from old age. The latter added, however, "Post-mortem examination often reveals extensive anthracosis in an otherwise perfectly healthy lung and no symptoms in life."

*Other sources.*—In the Rand gold-mines, so Mr. Alex. Richardson kindly writes, no animals are used for haulage purposes; some years ago a few mules were employed, but nothing is discoverable as to their health. Dr. Johnson<sup>5</sup> kept white rats continuously down a Witwatersrand mine in the dustiest spot, their conditions of life being much worse than those of the miners. They developed silicosis but not tuberculosis; their general health was quite unaffected. Rats breathe through the nose exclusively. In a discussion following this paper the opinion was expressed that if the rats had been brought up out of the mine regularly like the men they would have developed hardly any silicosis in five years.

In Cornwall, Dr. Tonking, whose work on the local miners' phthisis is well known, tells me that there are no ponies underground in the Camborne district. In the St. Just area one mine uses them, but there, so Dr. Nesbitt is good enough to report, no silicosis or miners' phthisis exists, save a few cases returned from South Africa.

At Gartverrie, Scotland, the manager of the ganister-mine there (ganister, a component of firebrick, &c., is a great source of silicosis) tells me that men and horses work practically in an open quarry and that silicosis in either is unknown.

In a discussion following a paper by Dr. Haldane, F.R.S.,<sup>6</sup> Sir H. Cunningham said the dust<sup>7</sup> of the mines—this dust was not only coal, but also stone or shale put down to lessen risk of coal-dust explosions—did not hurt the pit ponies. Another speaker instanced a pony which had worked in very dusty parts of a mine for many years. It was shot, and on examination no dust was found in the lungs. Dr. Haldane related having examined coal-pit ponies killed in an explosion, and having been struck with the small amount of dust in their lungs, which were comparatively pink. He supposed that the ponies' noses filtered the dust off. Pit ponies all looked well and lived for many years.

Lastly, there is the case of the great Alpine tunnels, in making which men and horses were employed; it is certain that formerly both suffered a high mortality. The causes of death in the men are given as ankylostomiasis and "acute bronchial and pulmonary catarrhs." There is little mention of tuberculosis or chronic pulmonary disease. What the horses died from I have not been able to ascertain. But it is stated that there was a very high CO<sub>2</sub> content in the tunnel air, often exceeding 15 per 1000, so that the railway metals were chemically affected. This would probably lead to acute pulmonary ailments in the horses too; a certain incident related to me in connexion with coal-pit ponies seems, at any rate, to suggest so.

*Author's Investigations.*

My district contains many mines.

*Coal-mines.*—I have visited three, one employing over 200 ponies. What I heard and saw, with one exception, entirely confirmed the preceding literature. There were no lung ailments among them; they were hardly ever sick; they were invalided for old age; their average working life was 13 years; and so on. Certainly they all looked fat and well, and did not cough; many were obviously old. They never came to the surface except during a strike. The exception spoken of was that in one pit the stables had once, for the sake of proximity to work, been put in the "return" air-way. The ventilation of a coal-mine is artificial, and for this

<sup>6</sup> J. S. Haldane: The Effects of Dust Inhalation, Institution of Mining Engineers Annual Meeting, London, June, 1918.

purpose there are mostly two sides to a mine, separated by a double set of doors having a dead space between. On the one side is the incoming good air from the surface, on the other the outgoing or return current. The latter is stated not to be more dusty than the former, but to contain some  $\text{CH}_4$  and a higher percentage of  $\text{CO}_2$ . After these ponies had lived for a little in this chemically somewhat deteriorated "return" air, against which the nasal filter would be no protection, they panted and wheezed, and one or two died. On changing the stables back to the intake air-way the ponies regained their health. It is allowable to suppose that a good deal of the equine mortality in the old Alpine tunnel-making arose in this way.

**Ganister-mines.**—I have visited six mines and made inquiries as to six more. Of these 12, four employed ponies underground; the largest number at any pit was five. The reports were that the health of the animals was excellent. However, it appeared that the conditions as regards possibility of dust inhalation were better for the ponies. They being required for traction purposes, waited in the roadway while the men were engaged at near quarters with the mineral. This was so at three of the four mines, including the one in which human silicosis was most common. At the fourth the conditions under which human and equine workers were employed were described as being about equal. At this place it was claimed that an improved system of ventilation had practically abolished silicosis, but I was told that when the disease was common in the men nothing analogous was noticed in the ponies, and a mule had worked for 20 years in good health. In all these ganister-mines the ponies, unlike coal-pit ponies, were stabled above ground, coming up after a shift of work. The shallower depth and smaller extent of the workings facilitated this practice.

#### Conclusions.

It will be admitted that the trend of the above evidence is in favour of horses being much less liable to pneumokoniosis than man is, and that there is some reason to think their exclusive nasal breathing responsible for this. With this result may be usefully coupled another similar one already mentioned—namely, that horses are also much less prone than man is to tubercle, especially pulmonary tubercle.

Does the same explanation hold? At all events, it is made more likely by the way this comparison of human and equine pneumokoniosis has turned out. Laboratory experiments on phthisiogenesis have often consisted in making animals inhale or ingest dust, and mine experience is obviously superior, in actuality and correspondence to natural conditions, to laboratory experiment. Parenthetically, it contradicts the conclusions of the school of Calmette as to the alimentary origin of pulmonary tubercle, conclusions already assailed by Cornet, a fellow bacteriologist. For these coal-pit ponies, although their food is now brought down fresh to them every day or two, must, by living in a coal-pit for years and champing their bits when at work, swallow great quantities of coal-dust; they must swallow much more than the men do. Yet Dr. Haldane finds their lungs much less black than the men's.

The freedom of horses from pulmonary tubercle cannot, on the other hand, be explained by specific humoral insusceptibility, as witness the experiments of MacFadyean, Ravenel, and Griffiths of artificial inoculation of horses with tubercle, in which copious pulmonary lesions were produced or fatal results reached. Again, specific humoral insusceptibility to tubercle would explain nothing of horses' freedom from pneumokoniosis. Exclusive nasal respiration will explain both, and in addition the especial rarity of the pulmonary location of natural equine tuberculosis.

So much for deductions as to the pathogeny of tuberculosis and ordinary consumption. As for the bearing upon silicosis and miners' phthisis, it would be of advantage to have more observations. The number of ganister-pit-ponies is so very few, seeing that the district I have spoken of contains the majority of these mines in the whole country. Something should be learnt from exposing ponies or mules to the same conditions in South African and Cornish mines as produce human miners' phthisis, or to rather more severe ones. The white rat is not a good animal for experiment in this connexion, it being notoriously resistant even to artificial inoculation with tubercle<sup>7</sup>; whereas horses are distinctly less difficult.

In the prophylaxis of the grave South African silicosis it might be worth trying if measures like oral obturators, as also nasal irrigation after work, were possible in practice. In the few cases of clinical anthracosis and typical fibroid phthisis (other than those in men who work in stony parts of the mine, roof tenders, and so forth) that one meets with in colliers, I have been struck with the frequency with which such subjects showed a wide atrophic nose, which would be useless as a dust-filter. The effect of all continuous dust inhalation is to cause some slight degree of intranasal atrophy, but if a man came to this work already nasally atrophic his lungs would obviously be at a great disadvantage. Saenger<sup>8</sup> said that in workers in dusty trades those with wide nasal passages showed dust in the respiratory tract as far down as the trachea, which was not the case when the nasal fossae were of normal size.

I wish to express thanks to all of my informants.

## TUBERCULOSIS FROM A WEST INDIAN STANDPOINT.\*

BY JOSEPH GEOGHEGAN, M.B., F.R.C.S.E.,  
TEMP. CAPTAIN, R.A.M.C.; SURGICAL SPECIALIST, BELFAST DISTRICT;  
LATE GOVERNMENT MEDICAL OFFICER, TURKS ISLANDS, ETC.

THE Turks and Caicos Islands form the southern end of the arc of the Bahamas, but are attached to the government of Jamaica. Grand Turk is the capital. The population, of 5615 by the Census of 1911, is of the usual original negroid stock with, in cases, a dilution of white blood; there are a small number of whites to whom the remarks here made do not apply. The people are of a hardy, sturdy type, usually good boatmen, living by work on the salt-ponds—which give the staple product of the Dependency—sponging, and plantation labour, the last in a restricted and limited way. The islands are very barren; water is scarce, largely dependent on the small rainfall. The climate is warm but tempered by cool trade winds.

#### Mortality from Tuberculosis.

During the quinquennium 1909-13, of the total deaths registered in Grand Turk, the percentage recorded as due to tuberculosis was 14.4, indicating about 4 per 1000 of the population. No information is available as to the other settlements of the colony as a whole.

The corresponding rate in England is under 1. In the 15 largest towns of Scotland the quinquennial rate<sup>2</sup> at slightly over 1½ (1.6) is the same as that for the United States of America.

Comparison instituted between these figures and West Indian statistics is not to the benefit of the latter. In Jamaica<sup>3</sup> the death-rate per 1000 is under 2; 3.5 for Kingston. In Grenada<sup>4</sup> for quinquennium to 1913 the percentage of deaths due to tuberculosis was 5.72; 10.41 for the town of St. George. In St. John's, Antigua,<sup>5</sup> 6.13 per cent. In Trinidad (and Tobago)<sup>6</sup> for quinquennium (1909-13) 2.1 per 1000; 5.2 for the capital, Port of Spain. In the Bahamas the disease is said to be rife. Dr. Godfrey<sup>7</sup> points out for British Guiana that—

"the crowded villages near Georgetown and along the west bank of the Demerara River show phthisical death-rates of 4.2 and 4.3 per 1000 living, while the less crowded and scattered villages of the east bank and of the sea-coast have lower rates, 2.2 and 2.3 respectively. On the sugar plantations, where overcrowding is forbidden and where regular life obtains, the average phthisical death-rate during the years 1907 to 1910 is 1.15 per 1000, while in 1911 the rate is 0.9, which compares most favourably with any civilised country."

The histories of two families illustrate certain aspects of the question; the number could be readily amplified.

Summed up, there is in one family the case of a girl dying of the disease; her mother is now affected; amongst the family a young man, her uncle, dies of the disease, followed in succession by his father and his sister, his sister's fiancé being left tuberculous.

In the second series instanced the disease commences in the death of a young man; then follows in fatal sequence

<sup>7</sup> See Cobbett: The Causes of Tuberculosis, Cambridge, 1917, p. 444.

\* Abridged from a report submitted to the Colonial Office.

first the father, then a brother, then a sister, all living and dying in the same house, and leaving affected a sister from the house and a brother living elsewhere. I have not been able to gain precise information as to how long the last has been in existence, but, be it the origin or the result, the inference remains.

In neither of the series recorded is hereditary predisposition or transmission suggested or known to my information, but in the distinct lines of infection illustrated is shown the impress of other factors.

#### *Causation.*

All West Indian observers agree in the opinion that the incidence of phthisis pulmonalis greatly overweighs other tubercular diseases which are comparatively infrequent. In this Dependency only two joint affections have come under my notice in nearly four years' experience, and the glandular condition is but seldom noted. The boiling of milk is extensively practised in the West Indies; in Turks Islands tinned milk is almost solely depended on. Though the infantile mortality rates in the West Indies are admittedly high—in Turks Islands for 1914 and 1915, 204 and 229 respectively—there are other factors applicable of a certain importance.

In view of the negligible appearance of the condition in children,<sup>†</sup> and of the precise fields of the respective bacilli, such a sweeping statement that all tuberculosis commences in infancy (Behring<sup>9</sup>) may have an element of truth in it, but it has no minimising influence on the fact that pulmonary tuberculosis is under suitable environment highly contagious in the adult. Accentuation is lent to the question of direction of contagion by recent views on the respective spheres of influence of the human and bovine forms of the bacillus. The great preponderance of the human type in the sputum of phthisis pulmonalis is emphasised by A. S. Griffiths.<sup>10</sup>

It may therefore be concluded that it is to the human type that the prevalence of pulmonary tuberculosis in the West Indies is due. The mode of spread is apparent. Given an original focus, with or without a susceptibility, hereditary or racial, the disease is maintained by direct infection in virtue of the general ignorance of hygiene, in particular, the closing of every door and window at night, and the stopping up of nooks and crannies. This is common throughout the West Indies. Only prolonged perseverance can overcome the hatred of fresh air at night.

Other factors may be briefly scanned. All the West Indian towns have high rates as contrasted with the country districts. Reliable information is not to hand, but the house ratio in Grand Turk is 4·7 by a recent census. Overcrowding would not seem to present locally the terrible features of slum life in greater centres. As a concomitant to overcrowding it will be obvious that when a water-supply is inadequate or defective for any reason personal cleanliness may not be of a high order. The intimate association in thoroughly unhygienic sleeping-places of a number of individuals leaves little to be desired from the point of view of the bacillus.

Poverty is an important aspect. The West Indies possess a varied and rich dietary scale, but in Turks Islands the food as a whole is limited in variety, inferior in nature, and deficient in freshness. Starchy foods predominate and proteins are limited. If any influence can be attributed to food as a causative factor in tuberculosis, the dietary habits common to the West Indies may permit views palpably in alignment with those culminating in Philip's Zomotherapy.

Sanitary conditions leave much to be desired. Public or personal hygiene is unknown in the class forming nine-tenths of the population, but in all distant and small areas sanitation is a vexatious problem.

#### *The Question of Prevention.*

The figures quoted are solely derived from the comparative death-rates, and case-mortality will vary under the effects of administrative control and therapeutic advantages. In England it is said that, subject to surveillance from a reasonably early stage, a high percentage of cures may be expected. Grant Andrew,<sup>11</sup> in his careful résumé of a long series of hospital figures, out of 800 cases records a mortality of only 19·3 per cent. Recent administrative attention cannot fail

to have a repressive influence on the existence of a disease so common that no middle-aged person but bears the stigmata of infection. It is only fair to contrast the West Indies in the possession of the necessities of therapy in this direction with Victorian England, and to express the hope that a similar impetus of attention will give commensurate results.

The present case-mortality amongst those of negro stock in the West Indies is admitted by all observers to be indubitably high. Osler points out that the negroes in the Southern States have an extraordinarily high death-rate, especially in the cities. Of eight cases seen in sequence in 1915 in Turks Islands, all in an early stage (save one from abroad who is now alive) and all under constant supervision, no less than six were dead by March, 1916. Phthisis in Turks Islands has a most fatal complexion. Rather than that the disease is universal and widespread, the view should be taken that it is more fatal than frequent.

West Indian tuberculosis stands, therefore, in certain respects in contrast with English. This point is of high importance, since it must presumably be correlated either with an absence of therapeutic possibilities or with a special lack of immunising power in the negro. Whatever relation subsequent research establish, there can be no question but that attention to personal hygiene and public health must have a marked effect. Backward the West Indies may be at present, but the efforts recently begun cannot fail eventually to produce good results. Methods dissimilar to those suitable for England are needed. The people are a different race and must be approached in a more elementary manner. The actual infective danger of phthisis is decidedly greater than in England, from deficient sanitation, from hygienic ignorance, and from greater susceptibility; phthisis is, further, the stronghold of tuberculosis in the West Indies, and once successfully combated the other forms do not seem likely to give rise to serious concern.

The presence of such devitalising influences as malaria and ankylostomiasis and the difficulties of administration are not lightly to be ignored. Taking everything into consideration it must be admitted that the death-rates, while in cases remarkably low, preserve a fair average. St. Lucia with 17·4, St. Vincent with 17·56, Grenada with 19·27, Cayman Islands with 7·1, and Turks and Caicos Islands with 14·0, may be placed in contrast with Jamaica with 25·1, the Bahamas with 26·7, British Honduras with 24·2, and British Guiana with 29·2,<sup>12</sup> but there are usually special circumstances applicable in each case which must modify any stricture. The references indicate that the West Indies cannot be expected at present to maintain other than a fair standard. There is a fruitful field for investigation in the comparative study of tuberculosis in the different colonies, of which certain features in common have already been established.

Consideration of any tropical problem cannot fail to recur to the question of climate. It is, I believe, accepted that climate has little or no relation with the causation of tuberculosis. Taking, however, such a group as the Turks and Caicos Islands, even granting the unfortunate series of conditions noted, where the days are almost perpetual sunshine—perhaps the best and certainly the cheapest disinfectant known—there is an inclination to demand greater confirmation of such a statement. The effect of a few degrees of latitude on the sum of the obscure metabolic processes that make up life is well exhibited in the biological adaptations to very varying conditions that will readily recur to the mind. Man and the tubercle bacillus inhabit the known world, though it is said that the Bedouin of the Sahara and the Eskimo of the Far North are free of such an unnecessary adjunct. Is a tropical climate better suited to the tubercle in the lung or to the tubercle bacillus? Or is it that, in the extra-corporeal life of the bacillus, there is an optimum of climate for the parasite as well as for the host, which need not necessarily coincide?

<sup>†</sup> I have never seen a case of abdominal tuberculosis in the Turks and Caicos Islands.

## INFLUENZA-PNEUMONIA:

## THE BACTERIOLOGY OF THE COMPLICATIONS IN FATAL CASES.

By OLIVER HEATH, M.A., M.B., B.C. CANTAB.,  
CAPTAIN, R.A.M.C. (T.C.).

(From the Laboratory of the 5th Northern General Hospital.)

FROM the recent preliminary publication by Rose Bradford, Bashford, and Wilson<sup>1</sup> it appears that they have definitely unearthed the prime causal organism of the late "influenza" epidemic. On the other hand, it is not so obvious that this "filtrable virus" is the cause of the numerous deaths.

The work here recorded was commenced in October, 1918, when the epidemic had reached serious proportions in the area served by this hospital. It was undertaken solely with the idea of determining and isolating the micro-organisms responsible for the fatal cases, with a view to preparing an efficient vaccine for prophylactic and curative purposes. Attention was concentrated mainly on material obtained post mortem as soon after death as "leave" could be obtained, and on specimens of the serous fluids taken during life with aseptic precautions. The examination of sputa was not followed up to any great extent owing to shortage of staff, and because it was noticed early that frequently the most serious cases did not expectorate.

*Bacteriological Findings.*

*Post-mortem examinations.*—The bacteriology of the pericardial and pleural fluids and the lung "juice" or pus is recorded below. Four points attracted notice: 1. The frequency with which fluid was found in the serous cavities. 2. The invariable presence of red blood cells in the serous fluids, with a variable "quantum" of pus and living bacteria. 3. The large proportion of fatal cases which came from "low category" units—10 out of 16. 4. The frequency with which pneumococcus, streptococcus, or a diplo-streptococcus was isolated: from all except one, and in this one pneumococci were seen in the films, but the cultures were overgrown by a coliform *B. Morgan* No. 1.

In the British and foreign press attention has been directed to hæmorrhagic lesions of the serous membranes. Attention is here drawn to the frequency with which one finds, post mortem, an "inflammatory" fluid, containing living bacteria, in both pericardial and pleural fluids.

The type of coccus referred to as a "diplo-streptococcus" was a Gram + coccus, usually strongly capsulated, frequently lanceolate and suggesting pneumococci, more often rounded, but often (especially in lung "juice" or pus) showing chain formation. Pleomorphism was marked. Large and small cocci, Gram + and Gram - cocci, and large round or pear-shaped forms—"involution forms"—have all been seen in one chain of cocci. In one sputum films showed only large pear-shaped forms, while the cultures yielded a nearly pure growth of this "diplo-streptococcus." In culture this coccus grew best on media containing blood, more sparsely on agar. The colonies are pyramidal and gelatinous-looking, and about the third day are flattened with a central "boss" which may disappear later. Occasionally gelatinous lumps form, giving the appearance as if one had broken the medium in planting the culture.

The results obtained from these examinations are now set out, the organisms isolated being indicated under (a) pericardium, (b) pleura, and (c) lungs:—

- No. 1 (aged 23).—(a) and (c) *Pneumococcus* (pure); (b) —.  
No. 7 (aged 19).—(a), (b), and (c) *Pneumococcus*.  
No. 16 (aged 19).—(a) *Pneumococcus* (pure); (b) —; (c) *B. influenzae*, *pneumococcus*.  
No. 17 (aged 30).—(a) and (b) *Pneumococcus* (pure); (c) *pneumococcus*, *B. influenzae*.  
No. 18 (aged 28).—(a), (b), and (c) *Pneumococcus*.  
No. 19 (aged 27).—*Pneumococci* seen in films from plate, but all cultures overgrown by *B. Morgan* No. 1.  
No. 23 (aged 20).—(a) *Staphylococcus*, *diplo-streptococcus*; (b) —; (c) *diplo-streptococcus*, *M. catarrhalis*.  
No. 24 (aged 20).—(a) and (b) *Pneumococcus* (pure); (c) *pneumococcus*, *B. influenzae*, *M. catarrhalis*.  
No. 40 (aged 35).—(a), (b), and (c) *Diplo-streptococcus*.  
No. 41 (aged 19).—(a), (b), and (c) *Diplo-streptococcus*.  
No. 42 (aged 38).—(a), (b), and (c) *Diplo-streptococcus*.

No. 51 (aged 40).—All cultures yielded *diplo-streptococcus*, a short *streptococcus*, a small Gram - coccus.

No. 56 (aged 27).—All cultures yielded *streptococcus*, *staphylococcus*, *M. tetragenus*.

No. 57 (aged 25).—(a) *Staphylococcus*; (b) *staphylococcus*, *M. catarrhalis*, a *streptococcus*; (c) (unfinished owing to illness).

No. 58 (aged 51).—All cultures yielded *diplo-streptococcus* and a few colonies of *staphylococcus*.

No. 60 (aged 30).—All cultures yielded *diplo-streptococcus*, a *streptococcus*, *staphylococcus*.

The sputa of five of the above were examined during life.

No. 7.—Minute quantity. Purulent. Many pneumococci seen in films and isolated in pure culture.

No. 16.—Purulent. Many *B. influenzae* and a few pneumococci in films; both isolated in pure culture.

No. 19.—Purulent. Pneumococci seen in films of sputum and of plate-cultures, but cultures overgrown by a coliform bacillus.

No. 40.—Slightly purulent. The *M. catarrhalis* and a few pneumococci seen in film. *Pneumococcus* isolated in pure culture.

No. 51.—Mucopurulent. A few cocci resembling pneumococci seen in film. Cultivations not made.

*Bacteriology of serous fluids during life.*—Two examinations were made of pericardial and two of pleural fluids taken during life. The findings are now shown.

No. 12 (aged 34).—Fluid from pleura; purulent ++ *pneumococcus* seen; *pneumococcus* isolated.

No. 39 (aged 26).—Fluid from pericardium; purulent ++; *diplo-streptococcus*, *streptococcus*, and *staphylococcus* isolated (two examinations).

No. 50 (aged 25).—Fluid from pleura; slightly purulent; *staphylococcus* and diphtheroid bacillus isolated.

Notes on above cases:—

No. 12.—Sputum mucopurulent. Pneumococcal-like organisms not seen. Cultivations not made. Patient recovered.

No. 39.—Sputum purulent. Diplococci resembling pneumococci seen in film. Cultivations yielded a nearly pure growth of the *diplo-streptococcus*. Patient died.

No. 50.—Sputum contained fresh blood and clots, and was purulent. Later was only purulent. Cultivations yielded a *streptococcus* and a diphtheroid bacillus. Patient eventually developed a gangrenous cavity in the lung.

*Examination of sputa.*—Forty-six were examined, and cultivations made from 20 of these. Organisms isolated were: *Diplo-streptococcus* or pneumococcus 19, *streptococcus* 1, *M. catarrhalis* 4, *B. influenzae* 3, a diphtheroid bacillus 2.

In film preparations from all cases (46): Cocci resembling pneumococci seen in 44, bacilli resembling *B. influenzae* in 7, *M. catarrhalis* in 8.

*Summary.*

1. Pneumococcal or streptococcal organisms were found in all of 16 post mortems; in 2 out of 3 serous fluids taken during life; and in 19 out of 20 sputa examined bacteriologically.

2. Emphasis is laid on the hæmorrhagic and infective nature of the fluids found post mortem.

3. Attention is drawn to the high percentage of fatal cases which came from "low category" units.

A MEETING of the medical practitioners of Blackpool, including members of the British Medical Association and non-members, was held at the Town Hall, Blackpool, on July 2nd. Dr. W. J. McL. Baird, honorary secretary of the Blackpool division of the British Medical Association, was in the chair. Among other matters considered by the meeting, Dr. John Brown brought forward the "forthcoming election of Direct Representatives on the General Medical Council." He said that, judging from a paragraph in the *British Medical Journal* of June 28th, the Association intended to run as its candidates the four gentlemen who were its nominees in the last election. He protested against the action, as he thought it unfair for the Association to monopolise the representation of the general practitioner, particularly as the Association did not represent more than half the profession, and many of its members were not in accord with its policy. The secretary for the Blackpool division said that out of some 120 medical men in the area of this division only 39 were members of the British Medical Association. The meeting unanimously resolved to support Dr. Brown if he decided to stand as a candidate.

#### A CASE OF ACUTE SEPTIC MENINGITIS OF OTITIC ORIGIN; COMPLETE RECOVERY.

By J. ARNOLD JONES, O.B.E., M.B., CH.B. MANCH.,  
F.R.C.S. EDIN.,

LATE TEMP. MAJOR, R.A.M.C.; AURAL AND LARYNGEAL SURGEON TO THE BRITISH FORCES IN MACEDONIA; SURGEON TO ST. JOHN'S HOSPITAL FOR DISEASES OF THE EAR, MANCHESTER, ETC.

THIS case is chiefly remarkable because of recovery.

The patient was admitted into hospital under my care on March 26th, 1918. A mastoid operation had been performed at a casualty clearing station 14 days previously. The notes stated that he had had sudden pain in the right ear with discharge; was delirious for a few hours; vomited. At the operation "offensive material" was found in the antrum and cells.

On admission on March 26th patient complained of headache and pain in the ear. Pus was freely draining through a small tube issuing from the mastoid incision and also from external meatus. Temperature, 99° F. No history of old-standing ear disease. On a daily antiseptic toilet the antro-tympanic cavity cleared up, and progress was good in every way. On May 14th he had an attack of benign tertian malaria which responded readily to quinine. From the 19th to 24th, diarrhoea; stools negative to bacilli and protozoa. On last date diarrhoea had ceased; complaint of headache and some aurial pain; slight mastoid tenderness. Temperature rose to 100°. On the 25th temperature normal, but other symptoms had increased. From examination with aurial speculum it was difficult to make out the anatomy of the operation cavity, so I reopened it under general anaesthesia. The antrum and tympanum had been thrown into one cavity and their roofs were absent, exposing a large area of dura covered with granulations. The antro-tympanic cavity was thoroughly cleansed and enlarged. No pus was found.

On May 26th patient had a much better night; the intense headache had gone. He now progressed well until June 5th, when he had a rigor; temperature 103°. Calomel gr. 3, aspirin gr. 15, followed by quinine hydrochloride gr. 20, given. On June 6th temperature 102°, pulse 94. Complained of headache; vomited in afternoon; no pain in ear; no mastoid tenderness; slight pain and rigidity back of neck; very slight Kernig's sign present. Reflexes normal; no definite signs of intracranial complications.

On June 7th temperature 101.2°, pulse 90; headache intense; slight retraction of head; Kernig's sign definitely present; no aurial pain. Lumbar puncture; a test-tube full of cerebro-spinal fluid under pressure and cloudy in appearance evacuated. Microscopical examination on the spot showed numerous pus cells. Subsequent report from pathologist showed Gram + staphylococci. Under general anaesthesia the antro-tympanic cavity was again reopened and thoroughly explored; no pus found. The brain substance of the middle fossa was explored with a needle; negative result. On June 8th and subsequent days patient was distinctly more comfortable. Headache and pain were absent, but he was drowsy; Kernig's sign persisted. The temperature gradually came down.

On the 12th there was a turn for the worse. Temperature rose to 103.6°; headache, pain in back and legs, was increasingly drowsy, and became slightly delirious. Another lumbar puncture; coconut-milk-like fluid withdrawn under pressure, containing far more pus cells than before. Subsequent report from pathologist showed Gram + diplococcus present. Immediate improvement in all symptoms followed. The temperature remained in the region of 102° for three days and then came down. On July 1st he began to get up from his bed, and when evacuated to hospital ship on the 14th, could walk several hundred yards without fatigue. Kernig's sign was much less marked.

Cases of definite septic meningitis with pus in the cerebro-spinal fluid which recover must be very rare. I have never met one in my own practice. There are two suggestive points. The organisms found in the cerebro-spinal fluid were of low virulence, and the resisting power of the patient was much weakened by malaria. Had his powers of resistance not been weakened by malaria, it is more than likely that no suppurative lesion of the meninges would have occurred. From over three years'

experience in Macedonia I have no hesitation in saying that complications of middle-ear suppuration are more common<sup>1</sup> than they would be in England under the same circumstances, and the reason for this is the deleterious effect of malaria on the resisting powers of the individual. Organisms of low virulence are thus able to bring about infections, but this very fact gives the patient a chance of ultimately overcoming them. Also noteworthy is the marked relief afforded by each lumbar puncture.

#### A CASE OF PERITONITIS FOLLOWING A NON-PENETRATING WOUND OF THE ABDOMINAL WALL.

By A. E. CHISHOLM, F.R.C.S. EDIN.,  
LATE CAPTAIN, R.A.M.C.

THAT peritonitis may result from a non-penetrating wound of the abdominal wall, with the abdominal viscera showing no gross lesion, seems proved by the following case.

##### Account of Case.

Gunner J. H., recently wounded, was admitted into hospital on Oct. 2nd, 1917; very collapsed and appeared to have lost much blood. Entrance wound, about  $\frac{1}{2}$  in. in diameter, in right buttock just external to posterior superior spine of ilium. Exit wound, about 1 in. across, in lateral sector of right iliac region. The patient was treated in the resuscitation ward for some time; no signs of improvement; it was decided to operate lest internal hæmorrhage was going on.

I opened up the anterior wound and found that the right lateral peritoneum was exposed in track of missile. Careful examination by Lieutenant Camps, who assisted, and myself, revealed no penetration of abdominal cavity. The right iliacus muscle was severely lacerated. Also fracture of the right iliac bone, involving separation of greater part of crest with part of body; comminution not very great. The damaged tissue was cut away, but not in region of exposed peritoneum, as it would have necessitated opening the abdomen. Bipp was rubbed gently, in a thin layer, into the raw surfaces. The muscles and skin were partly closed in layers, but greater part of wound was left open and very lightly packed with gauze. The entrance wound was then dealt with, the edges being excised and subjacent injured tissue clipped away; bipp was applied. Prior to operation a catheter was passed; small quantity of clear, rather concentrated urine was drawn off; urine not examined.

On the following day the patient seemed better; rather persistent vomiting. It is unnecessary to detail general treatment; various remedies, including alkaline treatment, were employed. On the morning of Oct. 4th patient was much worse. 1 c.cm. of pituitrin was given hypodermically and sodium bicarbonate and glucose solution intravenously. Death took place about midday. During all this time very little urine passed. There did not seem any very definite indication to open the abdomen, especially as one felt certain that the parietal peritoneum had not been punctured. The man would almost certainly have been unable to stand such a procedure.

*Post mortem.*—The following conditions were found. Peritonitis, apparently rather subacute, involving chiefly lower half of small intestine, pelvis, and region of cæcum. There were a good many plastic adhesions and patches of adherent lymph; small quantity of dark reddish semi-purulent fluid in pelvis. No *B. coli* infection smell. The stomach was not distended; tendency for intestines to be somewhat collapsed, except jejunum, but this was not actually distended. The bladder contained only a little fluid. The appendix was bound down over brim of pelvis by a recent soft plastic adhesion; otherwise appeared healthy. The parietal peritoneum in relation to the wound was very carefully examined; no perforation found. The small intestine was carefully examined from the duodeno-jejunal flexure downwards; no perforation; cæcum and ascending colon also appeared intact. The rest of the large intestine, not in relation to the wound, appeared whole. On opening the abdomen no free gas was detectable. The kidneys appeared rather cloudy. A swab from fluid in the pelvis was taken, but there had been already contamination, being taken on a second examination.

##### Inferences.

It would seem that the intraperitoneal infection must have taken place in one of three ways: 1. By direct spread of infection from the wound through damaged parietal peritoneum. No swab was taken from the wound, but on the day after operation it looked fairly clean. 2. By

<sup>1</sup> See also THE LANCET, 1918, I, 704.

escape of infection through a perforation in the bowel. But one has good reason that no such perforation existed. 3. By escape of infection through contused bowel. The absence of faecal odour in the peritoneal exudate tends to negative this. The probability is, I think, that the infection spread through the peritoneum from the wound.

The treatment of such a case presents difficulties. If the abdomen had been opened at the operation nothing pathological would have been found. Later the indications for opening the abdomen did not seem sufficiently clear; also the patient's condition did not warrant this.

The point arises, Should the soiled peritoneum in such a case be freely clipped away in spite of this involving the formation of a communication between the wound and the abdominal cavity? This idea is carried out by some in the knee-joint. A French surgeon informed me that if he found the outer surface of the joint capsule so soiled that the soiled tissue could not be removed without opening the joint, he freely excised it, opening the joint and afterwards stitching up the hole. Should this principle be applied to similar circumstances where the abdomen is involved? The proceeding would seem risky, and yet possibly not more so than in the knee-joint. Of course, it would never do to remove a large piece of parietal peritoneum in the wound, as it would be impossible to close the opening.

#### *Another Case.*

Since completing these notes another somewhat similar case has passed through my hands.

Private W. R., wounded on Feb. 27th, 1918; operation some 12 hours later. Entrance wound on right iliac crest anteriorly. No exit wound. Severe fracturing of right ilium and a good deal of laceration of right iliacus muscle. Peritoneum exposed in track of missile, but not lacerated. Patient was greatly shocked and had apparently lost a good deal of blood. An alkaline intravenous injection was given before, and a pint of blood after, operation. This consisted in cleaning up the wound and clipping away as much damaged tissue as was deemed wise, considering the patient's poor state. The parietal peritoneum was left intact. The wound was bipped and left open. Post mortem: Peritonitis with signs of bruising of bowel, but no perforation detected either of bowel or of parietal peritoneum.

### A CASE WITH COMPLETE CESSATION OF FITS RESEMBLING EPILEPSY.

BY H. DE C. WOODCOCK, M.D., F.R.C.P. EDIN.,  
D.P.H., &c.

THE following case came to my notice years ago.

A little Jewish boy had his tonsils removed. He lost a considerable amount of blood, and within a week or two he appeared to be an epileptic—that is, he had epileptic fits. Dr. A. H. Clark, of Morley, saw him, and he was treated with bromides without the slightest benefit. Dr. Clark and I were working together at that time, and we saw the case together at the boy's home. The boy on this occasion was undressed in my presence. As the sister took off the stocking from his right leg the patient went into an epileptic fit of the classical type, beginning on one side of the body and travelling to the other; clonic convulsions following tonic, and unconsciousness being complete. Recovery was speedy. On a subsequent visit the same phenomena were repeated, and it was then that the sister said: "Whenever we undress him he has a fit." As the treatment was doing no good it was discontinued. Patient recovered completely. I saw him some years later, and if the statement of his friends is to be relied on, there had been no subsequent attacks. It appears that peripheral irritation had induced the epilepsy, and that peripheral irritation had continued to excite the attacks.

The Jews are pathologically peculiar. The boy was highly intelligent and sensitive, and the attacks may not have been true epilepsy; all I can say is that they could not be distinguished from true epilepsy. Dr. Clark and I, not feeling secure in a position of clinicists in nervous diseases, did not publish the case at the time, but I have often felt that I must deliver myself of the description of this, to me, extraordinary case.

Leeds.

NEW HOSPITAL FOR EAST HAM.—The East Ham Hospital, which at present consists of 25 beds, is to be enlarged as a war memorial at a cost of over £30,000. Sir Samuel Waring has promised a donation of £2000.

## Medical Societies.

### ROYAL INSTITUTE OF PUBLIC HEALTH: LONDON CONFERENCE.

(Concluded from p. 13.)

#### III. HOUSING IN RELATION TO NATIONAL HEALTH.

IN the absence of Sir ASTON WEBB, the chair was occupied by Professor E. W. HOPE, medical officer of health for Liverpool. He said he was acquainted with the struggles to grapple with insanitary areas, which were the heritage of woe bequeathed by previous generations. The root trouble was the original vicious structural state of the houses. 22,000 tenements, many of the back-to-back character, and leading to blind alleys, were the monnment of Liverpool's rapid prosperity, when the one object was to crowd as many houses to the acre as possible, and the task of finding homes for the dispossessed which followed on improvements was left to the present generation, and it had been well grappled with.<sup>1</sup> The three-years mortality rate among infants in the insanitary areas before they were dealt with was 259, but in the three years 1916 to 1918 it had dropped to 162, and the phthisis rate had been reduced from 4 to 1.9 in the same time. The general death-rate was 37 in the old, 26 in the new. The birth-rate had always been high, averaging 45 for the three years prior to demolition, and 40 in the 1916 to 1918 period—almost double that of the country as a whole. These figures were in regard to a population of 12,000. Drunkenness had decreased, and the condition of the children had definitely improved. The housing question was inseparably mixed up with the welfare of the race, and he hoped for a continuance of interest now evoked by the housing schemes, with which, he hoped would be incorporated better and cheaper means of transport. The new houses for this prolific part of the population should include proper storage provision and appliances for domesticity.

#### *The Architectural Aspect of Housing.*

Professor S. D. ADSHEAD, F.R.I.B.A., dealt with the question from the architectural standpoint. He averred that the architectural aspect of housing seemed to have been largely lost sight of; it was an intangible quality, and might be termed the moral hygiene. He thought the new housing schemes should express the new organisations of society, as the old water-tight compartments of society were giving place to new conditions. There was need for standardisation of houses, but that did not mean mere repetition; the old days of 40 and 50 houses in a block of exactly the same construction were gone. There could be standardisation and yet such variations as reflected the social strata of the workers of the present day. Great variety could be produced by variants on only three plans, so that standardisation did not mean monotony. There had never been such an opportunity as the present for producing magnificent organised housing schemes, and he asked that the old-fashioned village should not be taken as the working model for the new, historically interesting though the former was.

#### *The Citizen's Ideals.*

Mr. NEVILLE CHAMBERLAIN, M.P., voiced the point of view of the citizen who was deeply impressed by the difference he saw in the best and the worst parts of a city, and whose earnest desire was to bring up the general average of health and comfort. He assumed that the citizen was willing to pay for his ideals; indeed, even economically, he would get back the expenditure on improvements by the diminished poor-law relief and other accompaniments of poverty and ill-health. The birth-rates of our cities were invariably highest in the economically worst parts, and schemes for betterment of those parts might lower the birth-rate; but that was counteracted by a lower death-rate too, and if the infants coming into the world had a better chance of surviving and living full and useful lives, the balance was certainly on the side of advantage. Large hopes had been raised by the mention of schemes which should transfer families from congested industrial districts to suburbs, but sufficient account had not been taken of three very important factors. First, it would take years

<sup>1</sup> THE LANCET, 1910, i., 1718; ii., 60.

to overcome the present house shortage, and until that was accomplished it was useless to talk of sweeping away the slums. In Birmingham there were 40,000 back-to-back houses. The second point was that large numbers of people did not wish to leave the slum localities, not because they were satisfied with their housing conditions, but they preferred improvement on the spot. Thirdly, a large number did not want to pay the rent which would be charged for new suburban houses. His point was that, even if all slum-dwellers wished to reside in suburbs, the provision for them would require years to bring about, and meantime every effort should be made to improve their present residences. Partial reconstruction would make an enormous difference, and this should not be left to private owners, some of whom, however willing, had not the necessary capital to carry out the needed structural alterations. Under Section 4 of the Housing Act of 1890 a local authority could pass a resolution that an area was unhealthy and that an improvement scheme should be carried out in respect of it, and in the new Housing and Town Planning Bill it was recognised that it ought to be possible to purchase lands in such area even before any improvement scheme had been formulated. The need was for a provision for compulsory purchase.

#### *Primary Importance of Housing Schemes.*

Mr. W. H. CADBURY said he agreed with those who said that every sovereign spent in the prevention of tuberculosis was of more value than £10 spent in sanatorium treatment and after-care schemes, and among preventive measures he considered that housing schemes came first, especially when due attention was given to through-and-through ventilation. Of 600 tuberculous soldiers who had been visited recently, 107 lived two families in one house. Preference should be given to soldiers who had fought in the war in letting the new houses. The birth-rate in Birmingham in 1865 was 39 per 1000; now—1918—it was 19.4, and it was still on the decline. Educated people seemed averse to bringing children into the world to face overcrowding, disease, and dirt. The Birmingham scheme was started with the stipulation that every house should have at least three bedrooms, but, yielding to pressure, a certain number of two-bedroomed houses had been arranged for.

#### *Earth Closets for Rural Areas.*

Sir RICHARD PAGET emphasised the importance of giving, in the new houses, the strictest scientific attention to the new needs of the community. He reminded the meeting that the main requirement in ventilation had been shown to be cool air in motion. The rural bungalow found great favour in his eyes, but with a cosy dressing-room, and this required a new design in cottage architecture. He also advocated a proper system of earth closets for rural areas and the use of the excreta on the garden. Sir William Crookes had estimated the loss of nitrogenous garden manure owing to the provision of water-closets at 14 million pounds per annum. He also advocated the use of labour-saving devices for the kitchen.

#### *Resolutions Approved.*

Mr. CHAMBERLAIN then moved the following resolution:—

This Conference is of opinion that while every effort should be made to provide the maximum number of houses on suburban sites, local authorities should be given further powers to enable them simultaneously to improve housing conditions in the central areas of large towns.

The further discussion revealed impatience at the delay in bringing the schemes about. The resolution was carried, 6 voting against. The following resolutions were also approved:—

(1) That the Conference is of opinion that the Housing and Town Planning Bill should include provision for the registration and more effective control of the subletting of dwelling houses, so that adequate provision may be made for proper washing, larder, laundry, and lavatory accommodation.

(2) That, notwithstanding the facilities already granted under the Orders of the Local Government Board in regard to the promotion of Housing and Town Planning Schemes, the Conference is of opinion that the Housing and Town Planning Bill now before Parliament should be passed into law without further delay.

(3) The Conference is of opinion that the erection of dwelling houses in the congested parts of cities and towns should be minimised, and that every facility should be provided to ensure their erection in open suburban areas, and that adequate, rapid, and cheap means of locomotion between the dwelling houses and places of occupation should be provided.

(4) That, in the view of this Conference, a wider and more liberal interpretation of the by-laws of many districts is necessary, and in others a more effective one, and that full discretionary power should

be given to the Ministry of Health to authorise modifications to meet local conditions. It is also of opinion that the improvement of the conditions of rural housing is of not less urgency than is that of the cities.

(5) The Conference recommends that the research now being carried out by the Government with respect to building materials and other details may be extended so as to include organised research as to the most efficient methods of ventilation, heating, sanitary and labour-saving devices, and their application to small houses in both urban and rural districts.

#### IV. MATERNITY AND CHILD WELFARE.

Mrs. Lloyd George had been invited to preside at this session, but found herself unable to do so.

Sir FRANCIS CHAMPNEYS (Chairman of the Central Midwives Board) occupied the chair, and opened the debate with an address on

#### *The Protection of Motherhood.*

He spoke first of the effect on the child of venereal disease in the mother. The immediate period to give attention to was that of pregnancy, parturition, and lying-in. Systematic attention to the questions of pelvic abnormalities and pelvic toxæmia, with pre-parturition examination of the mother, had resulted in a great increase in national health. Among the affluent the responsibility rested with the medical practitioner, in the case of the poor generally it rested with the midwife. The Central Midwives Board, however, discouraged diagnoses by midwives, but required them to inquire as to previous pregnancies, and if in any way abnormal to advise the expectant mother to seek advice at a hospital or other suitable institution. Should untoward symptoms occur she must report them at once; failure to do so was a penal offence and she was liable to be struck off the Register. Since the first operation of the Midwives Act in 1902 there had been a distinct improvement in these matters, but it had not been materially advanced, and it was desirable to ascertain in whose hands fatal cases continued to occur. It was a pity that the request of the Board that the death certificate should have a space for the name of the person who delivered the child was not granted, as this would have been very helpful. More information was also wanted as to the manner in which sepsis still occurred. There was need for many more obstetric institutions, so distributed over the country that no parturient or lying-in woman should be beyond the reach of one of them, and motor ambulances should be available. In 1914 there were 879,096 live children born in England and Wales. Stillbirths before 28 weeks of pregnancy were not yet registrable. If the average stay of the mother in an institution were taken as 25 days, it was calculated that 35,164 beds would be required in England and Wales per annum. At the foundation of the safety of the nation's motherhood was the training of the midwife, but the energies of the machinery set up by the Midwives Board were largely diverted into training women who never intended to practise midwifery; a serious position now that there was none too much material to train on. In 1918, of 19,357 midwives trained at approved institutions other than Poor-law, only 4640 notified their intention to practise it, a wastage, from this special standpoint, of 294,340 cases; and, adding other training centres, a total wastage of 356,420 cases! He considered that candidates should be required to bind themselves to practise as midwives for a definite term of years.

#### *The Protection of Infants and Children.*

Lady LESLIE MACKENZIE (Edinburgh) spoke eloquently on the question of the protection of infancy, pointing out how badly off were the many parts of the country where no gynaecologist was available; the thoughts on this subject were apt to be focussed on the city and the big town. All possible care should be given to every mother for the purpose of ensuring that she reared a healthy child; and this was rendered the easier by the fact that the Notification of Births Act allowed every public health authority to make whatever arrangements it thought fit to attend to the health of expectant and nursing mothers, and children up to 5 years of age. The present rate of death below 3 months of age was a disgrace to any civilised country. She insisted very strongly on the need in the young child of personal nursing by its mother, and the conscientious training of health visitors as well as nurses in the due care of the infant.

Mr. A. CARLESS dealt with the subject of the protection of childhood, pointing his remarks by reference to the case of Dr. Barnardo's Homes, through the doors of which

87,000 children had now passed. The death-rate had been phenomenally small, varying between 7.26 and 11.70 per 1000. He paid special attention to the question of sufficient and efficient food and plenty of sleep and exercise.

Dr. C. J. MACALISTER (Liverpool) said that the number of children attending the out-patient departments of Liverpool was larger than they could deal with. He described a scheme by which that city was to undertake a clearing-house arrangement for sending sick children to the most suitable institution for their particular ailment. He hoped to see established a great school for the study of children's diseases, which would probably take up research in children's ailments.

#### *Resolutions Approved.*

The sitting ended with the passage of the following resolutions:—

1. That this Conference views with great satisfaction the results already obtained from efforts made to promote the welfare of motherhood and infancy, and welcomes the prospect of fuller appreciation of the services which can be rendered by properly trained midwives and health visitors.

2. That the Conference considers the proper distribution of midwives and health visitors should come within the purview of the Ministry of Health.

#### V. THE TUBERCULOSIS PROBLEM UNDER AFTER-WAR CONDITIONS.

The concluding topic of the Conference was the Tuberculosis Problem under After-war Conditions. The chair was occupied by Professor HOPE.

#### *Mortality from Tuberculosis in England and Wales.*

Dr. H. HYSLOP THOMSON (tuberculosis officer for Herts) said that in 1911 there were in England and Wales 53,120 deaths from all forms of tuberculosis. In 1914 these had fallen to 50,298, but rose again in 1918 to 58,073, an increase common to both fighting forces and civilians, with a notable rise among asylum inmates, in one large asylum the 2 per cent. of 1914 rising to 11.7 per cent. last year. The increased mortality he attributed to the depleted resisting power of the population due to a prolonged war. One of the weakest links in systems for combating tuberculosis was the present method of notification, which included no information as to the danger of infection and the home conditions of the patient, and it placed no initial responsibility on the general practitioner. He considered that the services of the general practitioner needed to be extended in regard to the notification and prevention of disease. Dr. Thomson proceeded to discuss the various methods of prevention and treatment in detail. There should be segregation of acute cases, and adequate treatment of the advanced ones; he recommended their compulsory removal to a proper place. Much of the criticism of sanatoriums was due to the fact that too much was expected of them alone, though he admitted that the standard of such treatment throughout the country left much to be desired, both as to uniformity and efficiency. Sanatorium treatment could not be standardised, but certain general principles could be universally adopted. There was no other system which arrested the progress of the disease so well. No patient should be discharged from a sanatorium in whom there was further possibility of improvement. He dilated on the very poor provision for non-pulmonary cases of the disease, and entered into the question of domiciliary treatment, for which there was need of systematised effort on a large scale. His concluding remarks dealt with after-care.

#### *The Disease and its Treatment in Service Men.*

Dr. NATHAN RAW, M.P., spoke of the disease and its treatment among combatants. We must, he said, pay the highest tribute to the brave men who had fought for us and had developed tuberculosis. A large number of ex-service patients must have had the germs of the disease before the war, but the rigors and severities of trench warfare, and the great privations which soldiers had to endure were agents in stirring into activity what had hitherto been quiescent disease. He spoke of the desire of the Government to do everything possible for these men, and referred to the Commission which had been appointed to deal with the matter, of which he himself was a member. The number of Service men afflicted with tuberculosis was between 35,000 and 40,000, but a fair proportion were in the early curable stages, and many others were in a stage which permitted of their useful employment. He promised

that the provision for the ex-service men would be adequate, and he hoped the report of the Commission would soon be issued. A fact to be reckoned with was that a large number of the victims of the disease refused to enter a sanatorium, and he asked that every effort should be made to counteract the prevalent notion that tuberculosis, in any stage, was an incurable disease.

#### *Tuberculosis Communities.*

Dr. NOEL D. BARDSWELL (medical adviser to the London Insurance Committee) dealt with the question of tuberculosis communities. He said that unless the work of the various institutions could be associated with after-care, their work often fell to the ground. The factors which rendered ineffective the work of sanatoriums included the habits of the people, and economic questions, such as a living wage and housing accommodation. The root idea behind the tuberculosis settlement was the voluntary segregation of tuberculous persons in a community, which would allow of a more effective supervision than could be exercised at present. This, in order to be efficient, must be made attractive. Another important principle was the protection of the partially disabled worker from having to compete for his livelihood against physically sound men and women. These patients could not be dealt with to the exclusion of their families; hence the obvious need was for small village communities or something in the nature of garden cities. The prime object should be, not to give these patients seven or eight weeks of sanatorium treatment, but an opportunity of working under favourable conditions for the rest of their life. He believed the ordinary industrial occupations would prove more suitable in the long run than agricultural pursuits, and the opening was more extensive.<sup>2</sup> The case of the soldier presented a good opportunity to put the community system to the test; the soldier had his pension, and would be found very willing to take up some work. And what was found practicable for the discharged soldier could be applied to the case of the civilian.

Mr. H. J. GAUVAIN put in a plea for the non-pulmonary cases, for which nothing in an organised way had yet been done in this country. One or two large centres would probably suffice for all the cases of surgical tuberculosis in the country.

#### *The Necessity for Accurate Diagnosis.*

Lieutenant-Colonel W. MALLOCK HART referred to the disease as it affected the Canadian forces in the war, and pointed out the great importance of an accurate diagnosis. As director of the hospital for tuberculosis for Canadians here he could speak of its work. It had acted largely as a clearing centre, because many cases were sent back to Canada as soon as the disease was diagnosed. He felt in increasing degree the need for educating the general public with regard to tuberculosis; he had had experience in America with the results in educated communities and those in people who were ignorant on these matters. He did not consider that tuberculosis had increased as a result of men being on active service; indeed, he believed that the open-air life of the Army had preserved the health of many men who otherwise would have broken down. Of 900 cases he saw, 28 per cent. were in the incipient stage, 42 per cent. in a moderately advanced stage, 30 per cent. in an advanced condition.

#### *The Need for Combative Measures in Ireland.*

The Marchioness of ABERDEEN spoke on the question as it affects Ireland, pointing out the crying need of combative and remedial measures in the rural parts of the country. The educative campaign against tuberculosis which took place in Ireland a few years ago showed how quick were the Irish people to adopt the ordinary precautions, such as the open window. But the conference recently held in that country under the auspices of the Women's National Health Association showed that there was scarcely any provision for advanced cases of the disease; that conference unanimously urged the putting into force of compulsory notification of the disease. She concluded with a special and moving word on behalf of the Irish children.

#### *Return to Family Life a Factor in the Eradication of the Disease.*

Professor Sir G. SIMS WOODHEAD said he believed it was possible to stamp out tuberculosis; but there would be

but little chance of eradicating it unless the man who had been away could be brought back to his family life. It was not always the most robust person who was the most resistant to tubercle; and he urged that no one measure—such as open windows or good food—was sufficient; all means must be employed, and the machinery must not be allowed to hide the work.

The subsequent speakers included Dr. NASH, Dr. S. VERE PEARSON, Mr. DAG, Mrs. PALMER, Dr. SUTHERLAND, Dr. CECIL WALL, Mrs. SANDHALL, and Mr. BURNS.

#### *Resolutions Approved.*

The following resolutions were then put and approved:—

1. That in the opinion of this Conference schemes for the prevention of tuberculosis must be of general application, and it recognises that sanatoria, colonies, and other establishments for treatment and segregation are of the utmost value in the prevention of tuberculosis.

2. That the Conference recognises the obligation to provide not only for the tuberculous soldier, but for the tuberculous wife or child of the soldier or civilian or for any other member of the population.

3. That this Conference recognises the necessity for adequate provision being made for the treatment and training of sufferers from non-pulmonary tuberculosis, more especially in the case of adult sufferers, for whom no provision has hitherto been available.

4. That in the preparation of designs for the new houses which are to be erected in the near future special regard should be taken to the provision of the best methods of ventilating, heating, and sleeping accommodation, and a rigorous enforcement of by-laws designed to protect the dwellings from damp, with the object of combating and preventing tuberculosis by improving the general health of the community.

The Conference, which was carried on with much enthusiasm throughout and was very successful, concluded with the usual votes of thanks.

## ROYAL SOCIETY OF MEDICINE.

### SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

A MEETING of this section was held on June 20th, Dr. J. PORTER PARKINSON, the President, being in the chair.

Dr. HAZEL CHODAK showed a case of

#### *Chorea, Complicated by Gangrene of the Fingers.*

The patient, aged 12 years, was admitted to hospital in December, 1918, suffering from chorea of a week's duration. This was a first attack, and there was no previous history of rheumatism; no history of shock or overwork. Two years previously she had had diphtheria, with a had attack of tonsillitis during convalescence. The mother had had rheumatism and one sister had had chorea. On admission the patient, a thin girl, was found to be suffering from a moderately severe attack of chorea, all parts of the body being affected. There was very little loss of strength on the left side, but the right-hand grip was poor and feebly sustained. All reflexes were exaggerated. On examination of the heart the apex beat was found in the fourth space, half an inch inside the nipple line; a soft blowing murmur accompanied the first sound at the apex, and was conducted a short way towards the axilla; the second sound was accentuated at the base.

Ten days after admission the right hand began to go white and the finger-nails blue, though the hand did not actually feel cold to the touch. The onset might be described as rapid rather than sudden, and it was fully a week before gangrene of the finger-tips and half of the thumb had definitely set in. During this time the pallor spread up the forearm. There was no pulse at the wrist, but the brachial artery could be felt pulsating about half-way down the upper arm, and after a time there was distinct pulsation of the superior profunda artery. The pain, which was also gradual in onset, became very severe after the first few days, and could only be relieved by morphia. Meanwhile the cardiac signs showed changes in degree rather than in kind. The systolic murmur became much louder and rougher, while the second sound at the aortic and pulmonary areas was markedly accentuated. At first the apex beat remained within the nipple line, but in a few days it was found to be displaced slightly outside the nipple line. The pulse, however, remained at about 80, and was never increased in frequency, except occasionally when the pain had been very severe. The temperature throughout never rose above 99° F., and was rarely as high as that. Later still, the brachial pulse slowly disappeared, and the brachial artery could be felt like a thick cord along the arm. The little finger recovered, and lines of demarcation gradually formed on the remaining fingers. The ball of the thumb appeared at first to have escaped, as the discoloured skin peeled away from it, but there must have been considerable damage to the muscle, followed by contraction of the scar tissue, which had led to considerable deformity of the thumb. The choreic movements subsided rapidly soon after gangrene was established. The heart signs also disappeared, but much more gradually.

The question of interest in this case was the exact cause of the gangrene. The three possible causes of gangrene complicating chorea were: (1) Embolus; (2) arteritis (leading to thrombosis); and (3) arterial spasm (resembling Raynaud's disease). Raynaud's disease was mentioned as an infrequent complication of acute rheumatism, and might lead to local gangrene, but in this case there was extensive thrombosis which could hardly have been caused by mere spasm. As between embolus and thrombosis, the diagnosis was not easy. Dr. Chodak did not think that the absence of abrupt onset negated the embolism theory, as conceivably the artery might be only partially blocked at first. It was difficult, however, to feel convinced that there was ever any gross organic lesion of the heart, as the pulse and temperature kept so steady. At the time, however, the slight dilatation, the character of the murmur, and the loud accentuation of the second sound, made one believe that this was the beginning of a rheumatic carditis. There remained the supposition that there was a primary thrombosis in the brachial artery. Arteritis was not an infrequent complication of acute rheumatism, and although this was generally located in the aorta, there seemed no reason to suppose that the brachial artery might not be affected also. Such a condition might be speedily followed by thrombosis. In these cases the circulation was usually kept up by anastomosing channels, so that gangrene did not often occur. Probably in this child the general condition of debility and anæmia was a predisposing cause.

Dr. F. S. LANGMEAD showed a case of

#### *Scleroderma with Calcification in a Mongol.*

The patient, a boy, aged 4½ years, was the last child of a family of three. The mother was aged 42 years at the child's birth. The other children were aged 17 and 15 years, ten years elapsing between the last gestation and the birth of the patient. The mother said that she had always been healthy except that she had been anæmic. During pregnancy she felt quite well. The father and his family were described as highly strung and nervous. There appeared to be no neuropathic tendency in the mother. No alcoholic history.

The boy was small and appeared healthy at birth, but the mother noticed a similar discolouration and rash to that which was now visible on the knees, face, and hands. She was sure that the rash had always been present, but had varied in intensity from time to time. He had always been backward, sitting up at 10 months, walking at 1 year and 10 months. Walking had never been properly acquired, but had been feeble, with the legs apart. Until the last few weeks he had ceased walking altogether for two and a half years, and became unable to stand. In October or November, 1917, he was admitted to a hospital for "blueness" over the fronts of the upper arms; this had begun to spread to the chest over the pectoral muscles, but apparently improved considerably before his discharge. In December, 1917, he developed pneumonia, but made a good recovery. In June, 1918, lumps began to appear on the surface. At first they were quite soft and limited to the area over the biceps, but about two months later began to harden. More recently they had been noticed to spread inwards over the pectoral region. Flushing of the face varied greatly. It had been noticed for about two years, and was more marked on warm days. The legs had been noticed to be getting thinner for about six months, and about two months ago stiffness of knees and ankles supervened.

The child was a moderately marked example of the Mongolian variety of amentia, but with mental capacity above the average in such cases. The cheeks had a dusky-red, patchy appearance, the skin being somewhat atrophic and shiny. A similar blotchy bluish-red discolouration was seen on the fingers and hands as far as the wrists. The fingers were shiny and small, but no definite sclerodactylia had developed. The skin on the knees, extending upwards on the outer aspects of the thighs, and on the buttocks in the neighbourhood of the ischial tuberosities, was similarly affected. On the arms the discolouration had disappeared, and was replaced by white, firm, contracted skin, thrown into unevenness and puckers by subcutaneous nodules of sizes varying from minute seed-like bodies to plaques larger than a shilling. Some of these were confluent, others discrete. They were roughly linear in distribution and symmetrical, though rather more extensive on the left side than on the right. This condition had spread inwards over the pectorals, and backwards over the triceps on each side. On the left it reached somewhat farther down beyond the elbow and over the extensor carpi ulnaris muscle. A similar alteration of skin and subcutaneous tissue appeared in a roughly symmetrical manner in other areas, notably on thighs, legs, and in popliteal spaces. Some of the subcutaneous thickened areas were adherent to the skin, others were not. Some of the nodules were very hard, feeling

almost like bone. Here and there a nodule had caused redness and soreness of the overlying skin and slight scab formation. X rays demonstrated that the subcutaneous tissue in the nodular and thickened areas was sprinkled with small pleomorphic calcareous deposits. The muscle did not seem to be affected, but it was questionable whether they were not being gradually infiltrated from the subcutaneous layer. The movements were limited by the inelasticity and fixation of the skin. In addition there was some limitation of movement of the knees and ankles disproportionate to the subcutaneous hardening, probably due to accompanying synovial changes.

The points of interest were (1) the discolouration of the skin dating from birth, and later being replaced by scleroderma; (2) the calcification of the sclerodermatous subcutaneous tissue (calcinosis, petrification)<sup>1</sup>; (3) the associated arthritic changes; and with respect to the Mongolism, (4) the long period of sterility before the child was born.

Mr. PAUL BERNARD ROTH described a case of

*Apophysitis of Os Calcis.*

The patient was a boy, aged 14 years, who was said to have suffered for some years with double flat-foot. For ten years or longer he had had trouble with his feet, and for the last two years had had pains in his feet and ankles up to his calves on running. When seen by Mr. Roth he could only just walk from his house to the schoolhouse (ten minutes' walk). He had had various arch supports and appliances, such as thickenings of the soles and heels of his boots, electric baths and massage, but the pain still continued. On examination there was found to be a slight tendency to talipes valgus when he walked; all the pain was at the back of the heel and up the tendo Achillis; there were tender spots on both sides of the insertion of this tendon. He considered the case to be one of inflammation from trauma of the posterior epiphysis of os calcis.

Radiograms showed a cartilaginous gap with irregular ossification between the upper part of the epiphysis and the os calcis, especially marked in the left—the worse—foot, and some rarefaction of the bone at this point. As these radiograms confirmed the diagnosis, treatment by prolonged rest in bed was suggested, to be followed by gradually increasing spells of walking in boots with a rubber disk fixed to each heel, a pad of sponge rubber beneath each heel inside the boot, and a  $\frac{1}{4}$  in. valgus wedge of leather applied to the inner side of each sole and heel. Complete rest in bed for six weeks was followed by some pain, evidently due to stiffness and muscular weakness from his long rest. A month later he was able to walk, and even to run a few steps without pain. Radiograms showed that the wide cartilaginous band with irregular ossification had given place to sound bony tissue through its entire length, except a very small portion at the top (most marked in left foot) where the junction of the epiphysis was not quite complete.

Dr. EDMUND CAUTLEY showed a case of

(1) *Chloroma.*

The child had been first admitted to hospital for screaming and cerebral irritability, and was found to be feverish and apathetic, with right facial palsy and left-sided torticollis. These symptoms were rapidly recovered from, but after discharge a profound anæmia developed, bulging occurred in the temporal region, and the left kidney became palpable. Then pain was complained of in a hip-joint. The child became rapidly worse, and a month later nodules appeared on the head. The spleen and liver were enlarged and considerable increase in size of lymphatic glands was noticed. The red blood cells were 1,690,000; Hb, 25.5 per cent.; colour index, 0.79; leucocytes increased from 8000 to 14,000. Of these, the polymorphs increased from 1940 to 5845, the lymphocytes from 5660 to 7140. There were many features of chloroma, including a faint greenish tinting of the skin. The other possible diagnosis was adrenal tumour with secondary neoplasms in bone. In favour of this was the palpable left kidney which was noticed in the earlier stages. Skiagrams showed rarefaction of femora, vertex, and occipital region.

*Multiple Glandular Swellings.*

Dr. CAUTLEY also showed a case of Multiple Glandular Swellings in a child aged 1 year and 9 months. There was no family history of tubercle. The patient had been ailing since Christmas with diarrhoea, anorexia, and malaise.

Enlarged glands were found in the abdomen. Others, large and freely movable, were present in the neck and axillæ, especially in the right. Red corpuscles numbered 6,000,000; white 4800. A differential count was not abnormal. The Wassermann reaction was negative. The diagnosis lay between tuberculosis and lymphadenoma, and Dr. Cantley favoured the latter.

Dr. E. A. COCKAYNE showed a case of

*Trophedema of Leg.*

The patient was a boy aged  $8\frac{1}{2}$  years. There was no history of any similar condition in the family. The boy was normal at birth. At  $1\frac{1}{2}$  years there was a swelling, rather soft and lobulated, on the right side in Scarpa's triangle. Three months later some swelling of the right leg below the knee was noticed, and had increased ever since. When exhibited there was swelling of the whole of the right leg below the gluteal fold. The thigh was soft and the swelling in Scarpa's triangle could no longer be felt; it was 1 in. greater in circumference than the left. The lower part of the leg and dorsum of foot were very much swollen; circumference of right calf  $13\frac{1}{2}$  in., left calf  $9\frac{1}{2}$  in. The leg sometimes pitted on pressure. There was no nœvus and no cyanosis. The texture of the skin was normal. X rays showed no difference in the size of the bones. There was no lengthening of the right leg. The right side of the face was a little longer than the left and the right palpebral fissure was wider. The condition caused the child very little inconvenience.

Dr. ERIC PRITCHARD showed specimens from a case of

*Purpura.*

The patient was aged 1 year and 2 months, and had been fed on milk; no fruit juice had been given. The father, mother, and another child were healthy. The child had had pneumonia in December, 1918, a burn on the neck three weeks ago, and for the past week had had an ulcerated mouth. On May 11th a bruise on the left leg was noticed, which increased in size so rapidly that the patient was admitted to hospital on the following day. On admission the temperature was  $99.4^{\circ}$  F. The child was well nourished but extremely pale. There were large blue areas over the left leg (6 in. by  $8\frac{1}{2}$  in.) and thigh ( $2\frac{1}{2}$  in. by  $3\frac{1}{2}$  in.), a patch on the right leg (3 in. by  $3\frac{1}{2}$  in.), and petechial hæmorrhages over both. Enlarged glands were present on the left side of the neck, and discrete glands on the right side. Nothing abnormal was detected in the lungs. The heart was normal. The gums were firm and there was no ulceration; the teeth were very discoloured; the liver extended 1 in. below the costal margin. On June 12th the scrotum was very œdematous. A purple patch was present over the left foot. The child died on the following day.

*Post-mortem examination.*—There was an unhealed ulcer on the left side of the neck, due to a burn, consisting of two areas of about  $\frac{1}{2}$  in. diameter each, joined together. There was a subcutaneous hæmorrhage about  $\frac{1}{2}$  in. across on the chin, another area of about the same size on the right side of the neck, and large subcutaneous dark purple hæmorrhages on both legs. On the right side one hæmorrhage was about 2 in. in diameter over the patella, another large one was situated on the inner side and back of the middle of the leg, and all but joined a third one on the front and outer side, just above the ankle. On the left side the lower part of the leg was encircled by a hæmorrhage measuring about 4 in. from above downwards, and the epidermis above it was raised as a bulla. Both kidneys with their perirenal fat were the seat of extensive hæmorrhages, which were almost entirely cortical. Both testes were dark red from hæmorrhage. The only other hæmorrhage was in the middle portion of the thyroid gland. The thymus was a well-marked bi-lobed structure of ivory-white colour. The prepuce was œdematous, the liver pale, and the spleen slightly enlarged. The heart, lungs, pericardium, stomach, intestines, pancreas, and adrenals were all healthy.

Dr. LANGMEAD said that the appearance of the kidneys was exactly that of acute lymphatic leukaemia, and suggested that sections should be examined microscopically.

Dr. PRITCHARD also showed a specimen of

*Liver Abscess with Septic Umbilical Vein.*

The patient, a female, was aged 5 weeks and a full-term, breast-fed child. The father, mother, and four children were healthy. Vomiting always occurred at various intervals after the feeds, the vomitus being small in amount. The bowels were acting normally. On May 29th the vomiting became more frequent and larger in amount, and was of

<sup>1</sup> Vide F. Parkes Weber, Brit. Jour. Child. Dis., x., p. 97, at the end of which article references are given.

a greenish-yellow colour. The bowels were constipated. The child was admitted on May 30th looking very ill, though fairly well nourished. The temperature was 101° F., the pulse 132, and the respiration 42 per minute. The vomitus consisted of bright green material, the abdomen was distended and soft, there was no visible peristalsis or visible tumour, and the liver and spleen were not palpable. The heart and lungs were normal. On May 31st the stomach wash-out two and three-quarter hours after feed contained 1 oz. of green slimy fluid and an abnormal amount of acid. Rectal lavage gave clear fluid, not offensive. On June 1st a turpentine enema resulted in a slight yellow stool; another yellow stool, large in amount and undigested, contained a very slight trace of mucus. On June 2nd the temperature was 102° F., and the child was vomiting its broth and water. A small green stool was passed after a turpentine enema, which did not lessen the distension. Subcutaneous saline was given, but the child died.

Post-mortem examination showed the abdomen to be distended. The peritoneal cavity contained 6 oz. or 8 oz. of yellow fluid, and the intestines were loosely matted together by plastic lymph. The umbilicus had healed. When the liver was cut into, the part of the vein within the liver was found to be greatly enlarged and to have thick walls, so that it measured about  $\frac{1}{2}$  in. in diameter. The lumen, however, was almost obliterated, but some greenish pus exuded from it, in which Gram-negative bacilli were found. All the organs in the thorax were healthy, as were also the kidneys, stomach, and intestines. The hepatic flexure of the large intestine was situated, however, beneath the neck of the gall-bladder, the ascending colon lay close along the right side of the spinal column, the cæcum was situated over the right ilio-sacral articulation, and the appendix lay across the fifth lumbar vertebra. The spleen was rather firmer in consistence than usual. The adrenals were rather large and the right one was of reddish hue.

#### SECTION OF OBSTETRICS AND GYNÆCOLOGY.

A MEETING of this section was held on July 3rd, Mr. J. D. MALCOLM, the President, being in the chair.

In the absence of Mr. W. GILLIATT, his paper on

##### *A Case of Obstruction to Labour due to Ventrofixation*

was read by Dr. COMYNS BERKELEY.

The patient, a primigravida, aged 32, was admitted to Queen Charlotte's Hospital; she had been in labour five days and had had two attacks of uterine hæmorrhage. Examination showed a median sub-umbilical scar about  $3\frac{1}{2}$  inches long. The uterus was tense and asymmetrical, and the foetal heart was not heard. The cervix was displaced upwards, backwards, and to the right, and the uterus seemed to be in early tonic contraction. Cæsarean section was decided on as the best method of procedure, as on examination under anæsthesia the inaccessibility of the cervix, its size and rigidity excluded vaginal methods.

On operation, the uterus was found fixed to the anterior abdominal wall by a thick tightly stretched band about 2 in. long which was attached to the posterior surface of the uterus 1 to  $1\frac{1}{2}$  in. behind a line joining the uterine ends of the Fallopian tubes. There was marked axial rotation of the uterus through almost a quarter of a circle, so that the right-sided bulging mentioned above was at the expense of the posterior wall of the uterus. A stillborn child lay in a cavity formed mainly by the posterior wall of the uterus, which was stretched very thin. The head was delivered with difficulty from a sacculation in the uterine wall, in which it was tightly gripped. The patient recovered from the operation, but died some days later from septic endocarditis. The nature of the previous operation was unknown on admission, but was afterwards discovered to be an amputation of the cervix uteri and ventrofixation.

In the course of the discussion on Mr. Gilliatt's paper, Dr. LAPHORNE SMITH commented on the fact that the ventrofixation had been performed by attaching the posterior wall of the uterus to the anterior abdominal wall, and for this reason probably caused the obstruction. His practice was to make the attachment from the front wall, and below the line of insertion of the tubes.—Dr. BERKELEY concurred with this view, and the PRESIDENT suggested that, as a rule, ventrofixation should not be done in patients likely to become pregnant.

##### *Demonstration.*

Dr. EARDLEY HOLLAND gave a demonstration on the effects of excessive cranial stress in the foetus during labour, and on the mode of origin of tears of the tentorium cerebelli and cerebral hæmorrhage.

## TUBERCULOSIS SOCIETY.

### *The Annual Meeting.*

AT the annual meeting and dinner held on June 28th, Dr. HALLIDAY SUTHERLAND, the retiring President, outlined the origin of the society, whose members now numbered nearly 200. Membership was open to all interested in tuberculosis work, and with the signing of peace it was hoped that the society would occupy a place of importance in guiding and advising the coming developments of tuberculosis work.

Dr. F. N. KAY MENZIES said that five years ago, when the London County Council undertook to provide treatment for tuberculous persons, there were only a few beds and one or two dispensaries available. Now there were 900 beds, shortly to be increased to 1000, and every area in the county was served by a dispensary. The difficulties hitherto existing between the Council and the Insurance Committee would soon be overcome, and he looked forward to the union of his work with that of Dr. Noel Bardswell, the medical adviser of that body.

Captain W. E. ELLIOT, M.P., said that the representation of medicine in Parliament looked to the society for guidance as to the united opinion of tuberculosis workers. He foresaw developments in the treatment at industrial colonies, and referred to the Hairmyres Colony in Lanarkshire. More thought should be given to the mental capacity of tuberculous men who might be used in the development of electric force and similar enterprises.

### *Tuberculosis Work: Hopeful Outlook.*

Dr. NATHAN RAW, M.P., said that now the strain of war was over there was a very hopeful future to look forward to in tuberculosis work. The problem had been increased enormously by the return of thousands of tuberculous discharged service men, whom it was the country's duty to look after.

Dr. NOEL BARDSWELL hoped that the society would encourage expression of opinion from the junior branches of tuberculosis work. Their present remuneration was inadequate, and he thought that better prospects should be offered to them.

### *A Social Problem.*

Dr. H. DE CARLE WOODCOCK, President-elect, said that the tuberculosis problem was a social as well as a clinical one and demanded administrative ability on the part of the tuberculosis officer. His present position as assistant to the medical officer of health required readjustment. The tuberculosis officer should be in control of his own district and responsible directly to his public health committee. Referring to the new housing schemes, he thought that it would be the gravest mistake to build new houses and then to allow advanced cases to carry infection into them. Legislation was needed to remove infective cases from overcrowded areas.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.—A meeting was held on July 1st, at 11, Chandos-street, Lady Barrett, M.D., the President, being in the chair.—Dr. Octavia Lewin read a paper on Nasal Hygiene and National Health, and showed several cases of children successfully treated for nasal obstruction and deafness without operation. She also showed a case of stenosis of the posterior nares following an operation for adenoids in a child who was a diphtheria carrier. Dr. Lewin emphasised the fact that many operations would be avoided by proper attention to the nose and breathing.—Dr. Eleanor Lowry read a paper on the Nose in Relation to General Diseases. She referred to the importance of nasal obstruction and sinus suppuration in respiratory, digestive, and nervous diseases, and gave instances of mistakes in diagnosis and treatment of such cases. She mentioned some of the superstitions held by patients as to the connexion between gynaecological conditions and the nose and throat, and said that it was to be regretted that similar statements were still made in textbooks on gynaecology, and apparently copied into papers and books on the nose and throat.

THE LEAGUE OF MERCY.—Sir Frederick Green, K.B.E., honorary treasurer of the League of Mercy, has presented £10,000 to the League "in the hope that now that His Royal Highness the Prince of Wales has consented to become Grand President a new era of activity of the League may be inaugurated."

## Reviews and Notices of Books.

*A Text-book of Physiology.* By MARTIN FLACK, C.B.E., M.B., B.Ch. Oxon.; and LEONARD HILL, M.B., F.R.S. London: Edward Arnold. 1919. Pp. 800. 25s.

WE offer a very hearty welcome to the latest addition to the list of text-books of physiology. There is a vigour, originality, freshness, and attractive method in the exposition of certain parts of the subject such as one rarely finds in a text-book. The fundamental facts and theories are set forth in an easily understandable form with many an apt comparison and illustration. Although primarily written to meet the requirements of the medical student, it cannot fail to prove of value to the general practitioner. In the not very remote future "applied physiology" will come to be an integral part of medical education, and the authors have kept this end in view. Only a few of the great names and epochal dates in physiological discovery have found a place in the text. By abbreviating their work in this way the authors have, it is true, followed the example of Michael Foster, though we hardly agree with their decision. The student should know at least the century of Galen, Harvey, Galvani, Charles Bell, Bernard, Waller, and Helmholtz. There is nothing in the text to indicate whether certain important discoveries were made during this century or two centuries ago. We are unable to find an allusion to Bell's law. If it is in the text, it is not in the index. This may be the case, for the index is not complete.

The subject-matter is divided into 13 books—of unequal scientific and literary value—each of which is composed of several chapters. About 70 pages are given to General Physiology, while about 180 are devoted to Blood and the Circulation of Body Fluids. The description of Immunity and Allied Phenomena is terse and practical, and leads up to the students' later studies in these subjects. Book III., on the Circulation of the Body Fluids, is comprehensive and well thought out. The newer work on Cardiac Physiology is more successfully dealt with than in any text-book with which we are acquainted. The student ought to be familiar with the main facts of electrocardiology, and these are admirably set forth. One chapter is given to Effect of Change of Posture on the Circulation, a subject of particular clinical interest, and one which has not been treated adequately in the past. The Circulation in Special Parts is also excellent. Respiration occupies about 60 pages—not too much, considering the importance of the subject. We are glad to see that Dr. Hill's fundamental work is incorporated, as well as illustrated by several useful diagrams. The chapter on Principles of Ventilation is pithy and practical, and well worth perusal and study. We regard the chapters on Respiration as the most finished and the best in the whole book, or perhaps in any modern text-book.

Books V. and VI. (pp. 325–406) deal with General Metabolism and Dietetics, and the Processes of Digestion, and VII. with Special Metabolisms—e.g., proteins, carbohydrates, fat, nucleins. The spleen is very cursorily dismissed. These "books" have not the same merit as some of the others. There is evidence of imperfect revision, either on the authors' or proof-reader's part. Some of the rather vaguely described chemical processes might well be omitted. We are told that "appetite juice" "may be provoked by seeing, hearing, by smelling food"; "the injection of gastric mucous membrane of guinea-pig into rabbit may cause a specific cytolsin to form in the rabbit's serum"; and that gastric juice "is a clean watery liquid." "Meconium, the dark-greenish fæces passed by the newly-born child, are similarly acid in reaction, and inoffensive." Meconium does not find a place in the index.

The Functions of the Kidney, Skin, and Body Temperature form the next sections, and of these three the last is by far the best; indeed, it stands out as an excellent and practical exposition of the subject. We should like to have heard more of Cushman's recent work on the kidney. To the ductless glands (X.) only about 20 pages are given, illustrated by some good figures in the text; but even granting the controversial nature of much that is written about these glands and internal secretions, the subjects surely merit a more detailed survey. For the Tissues of Motion (XI.), including Animal Electricity, 40 pages

suffice. Galvani's period is not given, and the omission of the name of Du Bois-Reymond should make, to use the old tag, that philosopher turn in his grave. The Nervous System (XII.) occupies 185 pages, and of these less than six suffice for the "autonomic system," including several large illustrations. By omission of some details throughout the text space would easily be found for a fuller treatment of the central and sympathetic nervous systems, and perhaps also of the cranial nerves and sense organs. A curious slip occurs on p. 630—four of the ocular muscles arise "from the back of the eyeball." Several chapters on Growth and Reproduction (XIII.), which bring the book itself to a close, constitute an excellent suggestive epitome. Throughout the book histology is only introduced to elucidate definition.

We hope that in the second edition we shall find that the index has been revised and minor errors eliminated from the text. Perhaps the authors will change their minds, too, about the use of "drachms" as a fluid measure. Meanwhile, we think that this text-book of Flack and Hill—both experienced teachers and distinguished investigators—will prove most acceptable to medical students, and more especially to those who are preparing for the higher qualifications, not only on account of the marshalling of the main facts, but because the subject-matter is set forth in a readable and pleasant form, while its applications in practical medicine are steadily kept in view.

*Medical Annual for 1919.* Bristol: John Wright and Sons, Ltd. Pp. 675. £1 net.

THE editor is to be congratulated on the success he has achieved in the production, under difficult conditions, of this valuable record of medical progress. Some of the authors appear to have felt themselves cramped in their expositions of new work. This is inevitable where so much research has been carried out in certain special departments and where so many of the conclusions are still in a controversial stage. The discussion on war neuroses, for example, is obviously not a complete summary of the results obtained by different observers during the war. A good bibliography at the end of most of the important articles serves to correct this inequality, while providing useful assistance to those who wish to pursue a particular subject further. The articles on blood transfusion and amputations are adequate and well depicted. The illustrations in general, including five coloured plates, are clearly printed on good paper. The title-page of the book would be easier to find if the advertisements which precede it were removed or printed on coloured paper. The volume is, as usual, securely bound and of a reasonable size.

*Military Physical Orthopaedics. Part I.: Gunshot Wounds of Nerves.* By ARTHUR STANLEY HERBERT, M.D., B.S. Lond., Lieutenant-Colonel (Temporary), N.Z.M.C., P.M.O. of the Rotorua Orthopaedic Hospital, Government Balneologist. With 62 illustrations and 12 figures in appendices. Wellington: By Authority: Marcus F. Marks, Government Printer. 1918. Pp. 136. 6s.

THIS is a valuable little book. It represents the results of the experience of a surgeon who, being placed in charge of a large number of cases of nerve injury caused by war trauma, worked out his own methods of treating them remote from the great centres of military orthopaedics. It would have been still more valuable two years ago, but difficulties in printing prevented its appearance. The cessation of hostilities, however, will not affect the permanent value of the work.

Colonel Herbert seems to have been wonderfully successful in treating the disabilities following nerve injuries by means of very simple and cheap appliances, and particularly in his adaptation of the old principles of elastic traction to suit modern needs. Artificial muscles have a two-fold use. Firstly, by supplying a means of movement and preventing or correcting deformities, and secondly, by preventing stretching of paralysed or weakened muscles and thus helping them to regain function.

The importance of antagonist muscles is now well recognised, and by supplying artificial antagonists, elastic traction is of great value. In particular is the author's "long quadriceps strap," a very valuable addition to the

armamentarium of the orthopaedic surgeon. The great experience of the author as medical officer in charge of the New Zealand Government baths and sanatorium at Rotorua for 12 years before the war had well equipped him for the task which has since fallen upon him. The beautiful surroundings of the King George V. Hospital and of the sanatorium invite open-air treatment and it appears that nearly all cases are so treated. Colonel Herbert is to be congratulated on the ingenuity with which he has devised simple but efficient apparatus and on the good results achieved, all of which are well shown in the excellent illustrations of this book. It must not be supposed that because he insists on the value of these simple methods, he neglects the ordinary physiotherapeutic and electrical methods. These latter are adequately described and their use discussed.

From the fact that this volume is entitled Part. I. we hope that we may look forward to the appearance of another part dealing with injuries other than those of nerves.

*The Theory and Practice of Massage.* By BEATRICE M. GOODALL-COPESTAKE, Examiner to the Incorporated Society of Trained Masseuses; Teacher of Massage and Swedish Remedial Exercises to the Nursing Staff of the London Hospital. Second edition. London: H. K. Lewis and Co., Ltd. 1919. Pp. 265. 9s. net.

THE fact that only 15 months have elapsed since the appearance of the first edition of this book suggests that it has met a need. Our criticisms of the first edition have been largely met. Alterations in the chapters dealing with fractures, dislocations, and recent injury bring these matters far more nearly into accord with modern teaching. Colin Mackenzie's recent work receives recognition, with the result that the value of the chapters devoted to nerve affections is greatly enhanced. A new chapter on the after-treatment of war injuries is occupied in the main with a description of Mrs. Guthrie-Smith's well-known apparatus for the treatment of stiff joints, and the addition of a bibliography, though short, is welcome. Frequent smaller alterations in the text tend to convey a sense of confidence that was frequently lacking during the perusal of the first edition. The earlier part of the book still, we fear, conveys an unwelcome impression of stereotyped practice.

*Manual of Lip-reading.* By MARY E. B. STORMONTH. London: Constable and Co. 1919. Pp. 208. 5s. net.

Miss Stormonth's "Manual of Lip-reading" is intended to be an addition to a very limited branch of literature which it is by no means easy to extend. Teachers of lip-reading are so used to phonetics that perhaps they fail to realise how little the general public know about them. Any book on lip-reading intended for the use of the uninitiated should begin with a clear setting out of the phonetic system which is therein adopted. The omission of such a chapter is a great lack in Miss Stormonth's book. Mention is made of the need of natural speech, and stress might well be laid upon the need of distinctness of speech. No artificial way of speaking is required, but slipshod speech on the part of the teacher is a great drawback for the pupil. Apart from the caution given against the tendency of the teacher to exaggerate facial movements in voiceless speech, note might be made of the fact that the use of voice allows much greater natural play to the muscles of the face and throat. This is of considerable assistance to the learner and should not be ignored. Miss Stormonth seems to plunge at early stages into difficult words, and in dealing with the sounds set for each lesson treats them only as initial sounds. In Lesson I., for instance, treating of the sounds "a" and "p," a few preliminary easy words are given; then such words as "paralysis," "particular," and "paragraph" are introduced. Would it not have been equally satisfactory to have introduced the sounds in other positions, as in "tap," "clap," "happen," "appear"? The same remark applies to nearly every lesson.

Miss Stormonth has combined in a useful way the drill in words for the teaching of special sounds, with phrases on the "Look and Say" method. The two cannot be separated and give life to each other. Her advice as to the utterance and reading of sentences as a whole is very

important, whilst the use of word-building is well thought out and applied. She has faced, too, the difficulty of saving the adult learner of lip-reading from intellectual boredom, though her stilted and unusual sentences dealing with the "parson" and "factor" are rather tiring. The latter part of the book is most helpful in its classification of subjects and collection of proverbs and phrases, for in the teaching of lip-reading, unless a careful plan is laid, most unwelcome blanks are liable to reveal themselves at inopportune moments. The book may well prove of use, not only to amateurs, but also to those who are already engaged in teaching the art of lip-reading.

*Animal Parasites and Human Disease.* By ASA C. CHANDLER, M.S., Ph.D., Instructor in Zoology, Oregon Agricultural College, Corvallis, Oregon. London: Chapman and Hall, Ltd. New York: John Wiley and Sons, Inc. 1918. Pp. 570. 21s.

THE aim of this volume is to present the chief facts of parasitology as related to human disease in such a manner as to appeal to the general reader or to the laymen interested especially in the progress of preventive medicine and public health. Primarily the book is not one for the professed parasitologist. Without too greatly encumbering the text with roundabout phrases, scientific terms have been omitted or, where used, have been explained. The book, it is hoped, will supply the needs of teachers of hygiene and members of the public health service. The work, too, will have its interest for the medical man. As a result of the war there are probably more cases of tropical infections in the British Isles at present than at any previous time, and the author will have the satisfaction of knowing that the publication of his book in this country is peculiarly opportune. Recent advances in this particular branch of medical knowledge are embodied in the text and numerous sections are devoted to treatment. The book is divided into three parts, dealing respectively with protozoa, "worms," and arthropods. No bibliography is given. Instead there is inserted a list of "sources of information," which includes all the leading periodicals in which articles dealing with parasitological subjects appear, as well as a comprehensive list of books covering the field of parasitology; it is suggested that the student will find all the bibliographical references which he may require in these.

As would be expected from an American writer, a telling description of the economic ravages of the hookworm is incorporated. In the Southern States no less than 2,000,000 of the population are affected by this parasite, and "unlike many diseases, this one has no tendency to weed out the weak and unfit; it works subtly, progressively, undermining the physical and intellectual life of the community, each generation handing down an increased handicap to the next." In the treatment of this disease oil of chenopodium is rapidly supplanting other remedies like thymol, than which it is not only more efficient but also less dangerous. The book is well up to date, and there are excellent chapters dealing with malaria and trypanosomiasis, but while the results of Leiper's researches on bilharzia are included in the article dealing with schistosomiasis, we fail to find any reference to trench fever in the section devoted to lice and disease.

The book contains more than 250 illustrations, most of which have been drawn by the author either from specimens or from other illustrations. Pen-and-ink drawings have been used consistently in place of photographs, and, what is important in a work of this kind, in the majority of figures the magnification is indicated.

The author has succeeded in providing a really interesting and informing treatise on parasitology in its relation to human disease, and we think he goes far to succeed in his wish that his book may be instrumental in arousing the interest of more students in this branch of science to the ultimate end of enlisting a larger number in the ranks of its workers. He insists that the need of the present time is not so much additions to our knowledge as the efficient application of what we already know.

THE degree of D.Sc. hon. caus. has been conferred by the University of Philadelphia upon Professor A. Hopewell-Smith, M.R.C.S., L.D.S.

## JOURNALS.

*The Quarterly Journal of Medicine.* Edited by WILLIAM OSLER, J. ROSE BRADFORD, A. E. GARROD, R. HUTCHISON, H. D. ROLLESTON, and W. HALE WHITE. Vol. XII., No. 47. April, 1919. Oxford: At the Clarendon Press: London, Edinburgh, New York, Toronto, and Melbourne: Humphrey Milford. Subscription 25s. per annum. Double numbers 17s. net each; single numbers 8s. 6d. net each.—The present number includes the following papers: 1. Intrathoracic Pressure in Hæmothorax, Pneumothorax, and Pleural Effusion, and Effects of Aspiration and of Oxygen Replacement, by George C. Shattuck and E. E. Welles. The measurements of intrathoracic pressure were made with a water manometer graduated in centimetres. Readings showed that the pressure in a sterile hæmothorax changes little in the first 16 days after wounding, but in the case of small hæmothoraxes the respiratory excursion of pressure increases gradually during this time. Pressures observed in pleural effusions were similar to those in hæmothorax. By the simultaneous replacement of fluid by oxygen, volume for volume, the existing pressure in the pleural cavity could be maintained. 2. A Contribution to the Study of Contralateral Signs in Gunshot Wounds and Injuries of the Chest, by S. W. Curl. The author finds that contralateral signs are common, contralateral collapse being quite frequent. He emphasises the fact that the combination of physical signs supposed to be characteristic of solid lung is extremely fallacious and uncertain, since fluid effusions may give rise to identical signs. He considers that examination of cases by X rays, although helpful, is by no means sufficient for the differentiation of solid lung from a pleural effusion; and that the only safe guide is the exploring needle, and that this may fail unless used with discretion. He shows that in a small percentage of cases a fluid exudate may exist on the side towards which the heart is displaced, owing to the concomitant presence of a high degree of pulmonary collapse. 3. Two cases of Endocarditis due to *B. influenza*, by Archibald Malloch and Lawrence J. Rhea. In these cases bilateral broncho-pneumonia was present together with acute vegetative endocarditis. *B. influenza* was grown in pure culture from the terminal bronchi and from the centre of the vegetations in both cases. 4. The Therapeutic Action of Digitalis on the Rapid Regular Rheumatic Heart, by G. A. Sutherland. The writer illustrates his paper by accounts of ten cases in which he brings forward evidence to show that digitalis exerts a beneficial action even when there is no irregularity of the pulse. The drug, it is suggested, acts upon the auriculo-ventricular node and bundle, and where there is a sufficiency of sound contractile tissue in the ventricles leads to an effectual slowing of the ventricular rate. This contribution has a bearing upon a point at issue in a controversial correspondence which was carried on in THE LANCET in 1917. 5. Acute Leukæmia and so-called Mediastinal Lenkösarcomatosis (Sternberg), with the account of a case accompanied by Myeloid Substitution of the Hilus Fat of the Kidneys, by F. Parkes Weber. Most cases of mediastinal leukosarcomatosis have not been recognised as such until a post-mortem examination has revealed their nature. In a recent case the author was able by the microscopical blood picture and Roentgen-ray examination to make the diagnosis of the condition during life. The case is of further interest in that post-mortem examination showed the presence of deep-red, spongy, bone-marrow-like tissue in the hilus of each kidney. An informing survey of the literature accompanies the description of the case. 6. Observations upon Two Cases of Diabetes Insipidus: with an Account of the Literature relating to an Association Between the Pituitary Gland and this Disease, by E. L. Kennaway and J. C. Mottram. In this important paper data are given as to the composition of the urine and its molecular concentration in comparison with that of the serum in two cases of diabetes insipidus. The authors show that pituitary extract given by subcutaneous injection leads to a diminution in the amount of urine excreted, and recommend the injection of pituitary extract as a means of treatment. This anti-diuretic effect of pituitary extract appears to be due to its direct action upon the kidney. The restoration of a normal state of the urine when pituitary extract is given in diabetes insipidus provides, in the authors' opinion, the strongest evidence that the normal activity of the gland is concerned, in part at least, in regulating the secretion of urine. While the morbid anatomical findings, till now recorded in the literature, are insufficient to establish that diabetes insipidus is constantly accompanied by disease of the pituitary, there is much to suggest that diabetes insipidus is dependent generally upon such morbid changes. The authors point out, however, that disease of the pituitary can occur without any symptoms of diabetes insipidus supervening. 7. The Filter-passing Virus of Influenza, by John Rose Bradford, E. F. Bashford, and J. A. Wilson; together

with an Appendix of Clinical Notes on the Cases of Influenza from which the Virus was Recovered, by F. Clayton. This paper gives a detailed account of the extremely momentous investigations which the authors have been carrying out in their attempt to demonstrate the presence of a filtrable virus in the blood and other material obtained from cases of influenza.<sup>1</sup> That a filtrable virus was associated with influenza was first demonstrated by Nicolle and Lebaillly,<sup>2</sup> who by the subcutaneous inoculation into the human subject of a filtrate of sputum from a case of influenza produced a febrile illness comparable with the naturally acquired disease. The methods employed by the present writers are those of filtration, cultivation of the filtrate, and animal inoculation. The types of filters employed are the Berkefeld N and V and the Massén porcelain filter. The filter-passer has been seen microscopically in the filtrate and has been cultivated therefrom by the Noguchi method. The organism, which has definite morphological and cultural characteristics, can be demonstrated in the blood, sputum, and other exudates, as well as in the tissues post mortem by appropriate methods of staining. Inoculated into animals the pure culture reproduces lesions similar in character to those found in the disease in man—viz., the swollen, hæmorrhagic lung, the fatty change in heart and liver, the inflamed kidney, and the peculiar hæmorrhagic lesion in the voluntary and cardiac muscles. The organism, moreover, can be recovered from these tissues, so that the conditions ordinarily known as Koch's postulates are fulfilled. The whole horizon limiting our outlook over the field of infective disease has been enormously extended by the application of Loeffler and Frosch's method of filtration to the investigation of human infections, and the work of Sir John Rose Bradford and his coadjutors goes to show that a rich harvest awaits the patient worker in this field.

## New Inventions.

## A MODIFIED CATHCART'S APPARATUS.

THIS apparatus—in principle a Cathcart's but more compact and more easily applied—was devised in 1915 to cope with the spent fluid in the continuous irrigation treatment of wounds. It consists of a Canny-Ryall dropper connected to a metal T and siphon tube combined, the whole sunk in a wooden block which can be fixed to the patient's locker. The illustration explains the working principle. The amount of fluid necessary to create a continuous suction force is  $7\frac{1}{2}$  oz. per hour when draining an open cavity, and considerably less when the cavity to be drained is a closed one. It has proved useful in draining appendix and psoas abscesses, the bladder, gall-bladder, and chest, and also for removing filtrates in a small laboratory. It is made by Messrs. A. E. Braid, 30, Gower-place, London, W.C., and is sold with right- and left-sided blocks from which it is easily removed for sterilisation by boiling.

## The Liquor Traffic and the Public Health.

THE responsibility will shortly fall upon Parliament to decree the measures to be adopted in respect of the liquor traffic. The problem presented is an evergreen one in politics—it is to decide how and to what extent individual freedom shall be moulded for the public good; but where the control by the State of the sale of liquor is concerned the problem is one on which, to a greater degree perhaps than on any other social question, medical opinion has the right and the duty to speak with exceptional weight of authority. For the most serious results which ensue from the abuse of these beverages, and which, indeed, give to that abuse the importance of a social problem, are in the main ultimately reducible to the injurious influence of alcoholic excess on the bodily and mental health of the intemperate drinker. And this fact, that the effects of excessive drinking are chiefly manifest in disordered health, is not the only reason why the liquor problem in a special degree demands consideration from the medical point of view. The causes of intemperance, like its consequences, can only be justly appreciated when due regard is had to the fundamental facts concerning the action of alcohol on the body; and, as we shall have occasion to remark later on, the success achieved in dealing with alcoholism in this country in the last few years was obtained through the recognition of the truths of physiology in the enforcement of methods of regulation which were definitely and avowedly based on the indications of science. In all its more important aspects the liquor problem is essentially a medical problem, a problem of hygiene. And the new Commission, to whose jurisdiction the liquor traffic will be handed, will have to take this fact into consideration throughout.

The prevalence of alcoholism under the conditions obtaining to-day presents a striking comparison with its prevalence in the years before the war. It is, of course, to be understood that the statistical evidence which is available for such a comparison gives what is in certain respects an imperfect expression of the facts—that, for example, the deaths certified as due to alcoholism represent only a part, and doubtless a small part, of the mortality really attributable to alcoholic excess. This limitation, however, while it prevents us from regarding these statistics as any real measure of the amount of alcoholic mortality, does not affect their value as a standard for estimating the comparative frequency of intemperance in the two periods which we wish to compare. Taking, then, the year 1913 as representative of the state of things before the war, it appears from the official returns that under the then existent conditions of the liquor traffic there were in England and Wales 1831 deaths certified as due to or connected with alcoholism, and in addition to these there were 3880 deaths attributed to cirrhosis of the liver, while no less than 1226 infants under one year of age were suffocated in bed, well over a quarter of the latter fatalities

occurring on Saturday nights. Further, in those Poor-law infirmaries—unfortunately few in number—where records on the point were kept, there were 786 patients treated for delirium tremens. In the same year the number of convictions for drunkenness amounted to 188,877, being at the rate of 1 to every 135 of the population over 15 years of age. If we turn now to the figures for the year 1918, we find that deaths from alcoholism numbered 296, a reduction of over 84 per cent. on the 1913 level, and that deaths from cirrhosis of the liver fell to 1671, a decline of nearly 60 per cent., while deaths of infants from suffocation numbered 557—that is to say, they were more than 55 per cent. below what they were in 1913, and the predominant incidence of these deaths on Saturday nights, so marked in that year, no longer existed. Again, in the same institutions referred to above as furnishing returns of cases of delirium tremens, the number of patients treated for that disease in 1918 amounted only to 32, thus showing a decrease of no less than 95 per cent. on the figures for 1913. Finally, convictions for drunkenness totalled 29,019, or very little more than one-sixth of the number recorded in 1913. It might, perhaps, be suggested that the reduction in intemperance indicated by these figures is to be ascribed in part to the absence on military service of large numbers of adult males, but this explanation breaks down in view of the fact that the decrease has been equally or even more marked in the case of women. Thus deaths of women from alcoholism fell from 719 in 1913 to 74 in 1918, a reduction of nearly 90 per cent.; deaths from cirrhosis similarly declined from 1665 to 579, a fall of approximately 50 per cent., and in the Poor-law infirmaries keeping records of delirium tremens the cases of that disease in women, which numbered 214 in 1913, were only 6 in 1918. And, corresponding with this reduction in alcoholic disease and mortality, convictions of women for drunkenness declined from 35,765 to 7222, a reduction of practically 80 per cent. These figures provide adequate proof that during the war there has been in this country a real and substantial decrease of alcoholism; and since the greater part of the decrease followed immediately on the enforcement of the war-time regulations for the control of the liquor traffic, it is legitimate to conclude that these regulations were the chief agents in bringing about the improvement in national sobriety.

Alcoholism is, of course, a much bigger factor in the causation of disease and mortality than can be shown in official statistics, which necessarily represent only its most extreme and obtrusive results; and the improvement effected through the system of liquor control is correspondingly more important than is indicated by the evidence summarised above; but even if that evidence be taken merely at its face value, it will enable us to form some idea of the price, measured in terms of health and efficiency, which the community would have to pay for the full restoration of pre-war conditions in the liquor trade. Possibly public opinion would be prepared to pay that price, heavy as it is, if the regulations necessary for the control of alcoholism constituted a serious encroachment on public freedom and convenience. And on such grounds objection may, no doubt, be urged, and with some reason, against certain of the proposals which have recently been advocated under the guise of temperance reform, and notably against the method of direct limitation of the output of

liquor—a method which, when enforced by the Food Controller in the later stages of the war as a necessary measure for conserving cereal supplies, did, in fact, excite much irritation and unrest in the industrial classes. But no such criticism can lie against the policy of controlling alcoholism by regulating on physiological lines the hours and conditions of the sale of alcoholic beverages. This policy—in a form more stringent, maybe, than would be necessary or desirable in time of peace—was adopted by Lord D'ABERNON and the Liquor Control Board for the purpose of promoting the national efficiency during the war; it is a policy which does not involve any interference with the legitimate freedom of the temperate consumer of alcohol, and does not occasion any appreciable inconvenience to the general public—certainly none that is worth weighing against its great and unquestionable influence in promoting the well-being of the community. It contains, in a word, the minimum amount of restriction which is consistent with effective action in the control of alcoholism. And in this matter restriction of some sort is inevitable; not even the most extreme individualist has seriously proposed that there should be entire and absolute freedom in the production and sale of alcoholic beverages. The question is whether the restrictions which will be imposed by the new Commission are to be grounded on scientific principles and directed to safeguarding the health and efficiency of the nation.

### The Epidemiology of Pyogenic Infection.

No peace terms have been signed in man's warfare with bacteria, and there is little prospect of a truce with the minute vegetal foe. The ups and downs of the conflict have been closely studied in the case of typhoid, where success has fallen to man, and in so-called influenza, where the laurels must honestly be awarded to the other side. Dr. W. H. HAMER begins a report just published with the words: "The year 1918 stands out as a great influenza year." Of equal interest is the story of the struggle with the organisms which gain access to the body through obvious breaches of surface. While the war hygienist has taken some credit for the comparative absence of typhoid, typhus, and other such plagues from the Flanders front, no such congratulation is possible in regard to the epidemic diseases of wounds; for the wounded man, as Sir ALMRÖTH WRIGHT once reminded us, is simply a sick man with some surface discontinuity. Dr. W. W. C. TOPLEY's Goulstonian lectures, the second instalment of which we print this week, serve a useful purpose in bringing exact thought to bear upon the spread of bacterial infection from the standpoint of the bacteriologist. Three explanations are possible when confronted with epidemic disease: an increase in the power of the parasite to produce disease, a decrease in the resistance of the host, and some alteration in the surrounding circumstances furthering the transference of parasites from case to case. Dr. TOPLEY adds that the whole of biological knowledge is against the occurrence of a considerable epidemic in which the pathogenicity of the parasite and the resistance of the host remain constant, and rules out the third alternative as of minor importance. But he is speaking primarily of infections which enter the body through an intact surface.

There is, however, one organism, which has played a leading rôle in the drama of war wounds, in regard to the spread of which circumstances may chiefly be to blame. This is the type of hæmolytic streptococcus described in a paper by Mr. A. FLEMING and Dr. A. B. PORTEOUS on page 49, which has been held responsible for almost all the severe septic complications of wounds in Flanders and for all the streptococcal septicæmia. The number of its victims has been so large as to constitute an epidemic in the strict sense of the term, although an epidemic of very special character. Put briefly, this streptococcus was found actually responsible for a large number of deaths in those who "died of wounds," for a still larger amount of disability from continued suppuration, for various forms of infected skin lesions and joint infections, and, finally, for certain outbreaks of pharyngitis and laryngitis, as well as of pneumonia and pleurisy. An important committee was set up in 1918 by the Medical Service in France to deal with it. Any complete report on methods of prevention and treatment was first impeded by the rapid advance of the summer and then cut short by the cessation of hostilities. But the results obtained threw some light upon the origin of the infection. At a research casualty clearing station it was found that of patients admitted to the station a few hours after infliction of their wounds only a small proportion, under 15 per cent. in fact, were infected at that time with the hæmolytic streptococcus. Quite other was the experience at the base. Mr. FLEMING and Dr. PORTEOUS found that in a series of a hundred septic wounds remaining at a base hospital for over seven days this streptococcus was present in almost every case. Infection therefore presumably arose somewhere after the field dressing stage. Following up the search, they examined during last summer gauze packs removed from wounds on arrival at the base, and found the hæmolytic streptococcus in nearly every one when the man had been kept at the casualty clearing station for more than a week, whereas with the man sent straight on to the base the organism was present in 15 out of 75 excised wounds—that is to say, in only 20 per cent.

It would seem, as these authors state, a warrantable deduction that the streptococcal disease of wounds is in most cases a hospital infection, probably conveyed from patient to patient in the dressing of the wound. But while admitting the fact of infection at hospitals, other possibilities exist in regard to its conveyance than by manual transmission from wound to wound. At certain concentration camps in the United States of America it was noted that of new recruits entering the camp only a small proportion harboured streptococci in their throats, but after a short stay the majority were thus infected. It is at least possible that as with the meningococcus so with the streptococcus, some people are constant carriers of infection. Here Dr. TOPLEY is again enlightening. His conception is of a virus of a given disease being distributed fairly widely through the world as a comparatively harmless parasite on the human host, taking on during epidemic periods a new and sinister rôle. Under conditions of campaigning it may well be that the streptococcus carried in the throat gains an increased power of producing disease. Nor is the streptococcus the only pyogenic infection whose virulence or infectivity has become enhanced under war conditions. Mr. JOSEPH CUNNING's recent letter to our

columns on epidemic perinephric suppuration elicited from Sir THOMAS HORDER the opinion of a general rise in the incidence of staphylococcus infections. Furunculosis, syphilis, impetigo, blepharitis—all have been rife of late and individual cases more severe than usual. Soldiers returning home have apparently brought with them a more virulent strain of staphylococcus. Evidently pyogenic infections deserve the careful study of the epidemiologist.

## The Sense of Stability and Balance in the Air.

In the monograph on the above subject recently added to the valuable series of special reports published by the Medical Research Committee<sup>1</sup> Dr. HENRY HEAD, F.R.S., records investigations made upon both normal and abnormal subjects from the point of view of flying. Of particular interest is the section dealing with the sensations experienced by normal persons in heavier-than-air-machines. It is shown that conscious stability and comfort in the air depend primarily on the normal response of three groups of sense organs—namely, the vestibular apparatus, the eyes (including the eye muscles), and the proprioceptive system with its endings in muscles, tendons, and joints. Defective response from any one of these afferent end-organs disturbs the sense of equilibrium in the air, and leads to actions that affect the stability of the aeroplane. The report indicates that undue importance has hitherto been attached by many experts to the vestibular apparatus. It has become increasingly apparent to those connected with flying that although the sense of stability is dependent upon the integrity of the vestibular apparatus, the importance of the afferent impulses streaming in from eyes and the proprioceptive system must not be overlooked. An expert pilot finds it impossible to fly a machine with his eyes bandaged, and under these circumstances derives most of his information from cutaneous sensation and from the nerve endings in muscles, tendons, and joints. It is well known, as in the case of the recent Atlantic flight by ALCOCK and BROWN, that when the sense of vision is cut off the pilot loses himself in space, and may emerge from a fog or cloud with his machine at a steep angle or even upside down. Under these circumstances he is dependent almost entirely upon instrumental guidance for flying, and it may be that in future some instrument, such as Sir HORACE DARWIN'S "Turn Indicator," will be fitted to machines and be largely relied upon to give the pilot information in respect of his position to the earth.

Taking seriatim the chief points of interest brought out by Dr. HEAD: While flying an aeroplane an otherwise healthy man may suffer from disorders of vestibular and visual sensibility due to temporary causes. Such are giddiness through inability to regulate the tension in the middle ear with sufficient ease during a rapid descent, and defective visual orientation due to the development of heterophoria owing to disturbance in function of the eye muscles. Dr. HEAD shows that in some men, otherwise normal, rotatory stimuli produce a more powerful reaction than in the majority of their fellows. They become giddy easily. As children they could not swing with pleasure,

and some of them were habitually sick in the train. Such persons are not suffering from a pathological condition; their disability arises from the fact that sensory impulses from the semi-circular canals are not checked and controlled to the same extent as in the majority of healthy individuals. Consequently, when exposed to disturbances of equilibrium to which a normal man would adapt himself unconsciously, they suffer from discomfort, become giddy, and may even vomit in the air. Many who were giddy when first exposed to acrobatic evolutions succeed in conquering this disability. They learn to fly with ease, and the acquisition of this new facility is associated with control of the primary afferent impulses from the auditory and visual apparatus. Any condition which produces diminished control by the highest faculties over the activity of lower centres is liable, however, to lead to regression to the earlier mode of reaction. All healthy men can be affected if the intensity of the rotatory stimulus is pushed up to sufficiently high degree. This may occur either from the fact that the head is held in some unusual position, as, for example, when looking upwards during spinning, or the actual rotation may be mechanically increased in rapidity. In some cases the reaction to such excessive stimulation takes the form of giddiness, with or without nausea; in others it is associated with that withdrawal of consciousness known as "fainting." When a man is made giddy he is in a state of confusion with regard to his relations in space. In the preliminary stages of "fainting" his horizon is restricted and the world around disappears. Both states, pushed to the limits of endurance, end in unconsciousness.

Complete adaptation to disturbances of equilibrium in the air is associated with automatic control of the afferent and efferent activities of lower levels of the central nervous system. The normal pilot merely desires that his machine shall behave in a certain manner and the evolution occurs. This acquired facility can be disturbed by any condition which leads to diminished control. Just as a golfer can be "put off his game" by some physiological or mental state, so the aviator may lose his capacity to fly in consequence of conditions that vary so widely as a gastro-intestinal attack or domestic anxiety. Exhaustion, insomnia, the distress of war flying, anxiety, or fear can all lead to defective afferent and efferent control. Efficient automatic response is no longer possible, and the pilot begins to fly badly and to make bad landings. This loss of control over the activity of lower levels may be manifested, however, not only in bad management of the machine, but also in some dangerous reaction, such as "giddiness" or "fainting" in the air. When this abnormal reaction assumes the form of giddiness and nausea it is found in most cases that the patient has suffered from some discomfort when he first went into the air. Inquiry will usually reveal also that he was unable to swing with pleasure as a child, and that he tended to be sick when travelling by train. In this group rotatory impulses, when released from control, manifested their influence in giddiness, usually accompanied by nausea. When the reaction takes the form of "fainting" it is generally found that the subjects enjoyed their first flight and could swing with pleasure. Their resistance to vertiginous impressions was high and no excessive giddiness resulted, but they could induce the effects of shock with undue facility. Dr. HEAD

<sup>1</sup> Medical Research Committee Special Report, Series No. 28. Reports of the Air Medical Investigation Committee, "The Sense of Stability and Balance in the Air."

has performed signal service in drawing attention to the importance of regression in the airman, and showing that this may be produced by mechanical, physiological, or psychical causes.

In dealing with the tests for estimating the sense of balance used by the Examining Board of the Air Force Dr. HEAD criticises them adversely, since the results of the tests employed have, as is so commonly done, been entered frequently under heads such as "nervous debility," "muscle sense," and "vestibular stability" rather than under a heading indicating the actual tests employed. In his opinion the tests do not afford information in regard to the conditions they were designed to investigate. It is shown that the tests are of value in revealing the existence of some abnormal functional state, but are not otherwise an indication of ability to fly. Dr. HEAD, however, is not correct in his belief that the results of the tests employed have not been entered in detail on the admission forms of candidates for the Royal Air Force, and in this way has, no doubt quite unintentionally, done an injustice to the authorities concerned in his criticism of their records. We understand that many thousands of results of tests have been so entered, although, as indicated above, possibly under a wrong heading. A future study of these data will serve as a control to the experimental conclusions arrived at by Dr. HEAD as a result of the employment of the same tests. In conclusion, Dr. HEAD is to be congratulated on the way in which he has collected, described, and analysed individual examples of various abnormal states that may make their appearance during flight. The paper is a stimulating and original contribution to the medical aspects of flying.

## A Memorandum on Malaria for General Practitioners.

SIR RONALD ROSS and Lieutenant-Colonel S. P. JAMES have drawn up, for the information of medical practitioners, a booklet of suggestions for the care of malaria patients, which has been issued by the Ministry of Pensions and is to be obtained for 1d. from H.M. Stationery Office. An introductory section calls attention to the considerable number of demobilised men who have become infected with malaria during service abroad. These men will be entitled to receive treatment from Insurance practitioners, and it is the object of the Memorandum to bring within small compass particulars as to the nature of the disease, its clinical and other characters, the lines of treatment found to be most successful, and the measures necessary for preventing its spread. The medical man to whom malaria is reported must satisfy himself that the diagnosis is correct, supervise the treatment so as to cut short the attack, and notify the case to the medical officer of health. The Memorandum describes the three chief types of malarial fever, giving the main characteristics of benign and malignant forms, concluding with "pernicious symptoms" and the condition of "malarial cachexia." Differential diagnosis is considered clinically, microscopically, and in relation to the "therapeutic test." Quinine treatment and after-treatment are then dealt with at length. An appendix cites the relevant portions of the Local Government Board regulations in regard to notification.

## Annotations.

"Ne quid nimis."

### AMERICAN HOSPITAL FOR GREAT BRITAIN.

THE plans for the American Hospital are now in so advanced a stage that a meeting of the Governing Council will be held next week at the House of the Royal Society of Medicine, at which Lord Reading (who has accepted the Presidency of the Hospital) and the American Ambassador have promised to be present. Upon the signing of the Armistice last November the moment seemed ripe for bringing the project of an American hospital to the consideration of the medical profession in Great Britain, as well as to the American colony in London. Not only were the needs of the foundation of such a hospital obvious, but the exceptional opportunities of the moment were never likely to be repeated. The medical professions of America and Great Britain have hitherto worked too much apart, although each has much to learn from the other. The incidence of the war has brought them into closer contact. For two years American medical men have been attached to British units in the field, and have worked side by side with their British confrères upon the staffs of military hospitals in all parts of England and Scotland. The comradeship brought about by such friendly coöperation and interchange of scientific knowledge must be of vast importance in the future history of the two nations. A medical executive committee, consisting of Sir William Osler, Sir Arbuthnot Lane, Sir Humphry Rolleston, Sir John Bland-Sutton, Mr. J. Y. W. MacAlister, and Mr. Philip Franklin, sat in London and discussed the scope of the hospital; and at the Congress of the American Surgical and Medical Associations held in Atlantic City last month, Sir Arbuthnot Lane notified officially its establishment, pointing out that no more fitting monument could be raised to the fallen than a hospital designed to form the headquarters for American medical men who visited Europe for the purposes of post-graduate study. At this Congress the plans of the committee were received with enthusiasm, and Sir Arbuthnot Lane was assured by leading American medical men that their profession was keenly alive to the great value which such an institution might have as a centre for study and research.

A committee was then formed to establish the coöperation of American doctors upon a definite footing and to act in conjunction with the executive committee in London, and, if desirable, to operate under the National Research Council at Washington. This American Committee consists of Dr. George W. Crile, of Cleveland, appointed by the American Academy of Sciences on International Relations; Dr. W. J. Mayo and Dr. Charles H. Mayo, of Rochester, Minnesota; Dr. Albert J. Ochsner, of Chicago; Dr. Rudolph Matas, of New Orleans; and Dr. Franklin Martin, of Chicago, appointed by the American Gynaecological Association. This committee will send a delegate to London to assist the medical committee here in the detailed organisation of the hospital, which has been planned upon the most modern lines in every department of medical and surgical activity and of research directed towards every class of patient. A research institute, modelled upon the Rockefeller Foundation of New York, will form an integral part of the building.

The consulting staff will bring together distinguished members of the medical profession in the two countries. The visiting staff will be nominated by the executive medical committee.

The governing council of the hospital, which is likely to have for its patrons the highest personages on both sides of the Atlantic, consists of many prominent members of the American colony in London, including Mr. Walter Blackman, Mr. George M. Cassatt, Mr. R. Newton Crane, Mr. Wilson Cross, Mr. Clarence Graff, Mr. James Benson Kennedy, Mr. J. Blair MacAfee, Mr. George A. Mower, Mr. F. E. Powell, Mr. Henry E. Stoner, Mr. F. C. Van Duzer, and Mr. E. Bradner White, with Mr. Philip Franklin as honorary secretary.

#### LIGHT SENSE.

FOR a study on the "Performance of Night-glasses" we can recommend Bulletin No. 3, by L. C. Martin, D.I.C., &c., published for the Department of Science and Industrial Research by H.M. Stationery Office. The whole subject of light sense is indifferently understood. When we pass from bright sunlight to a dimly lighted room we can see nothing until our eyes have become adapted to the dark. This adaptation is supposed to depend principally upon some change in the relation between the bacillary layer of the retina and the adjoining pigment, and takes three-quarters of an hour or more to become complete, and in the second place upon the dilatation of the pupil, which occurs very rapidly. It is a curious fact that the fovea is physiologically night-blind, for a fully dark-adapted or scotopic eye is found to have a central scotoma; round the fovea is a ring that is most sensitive to light, and beyond this ring the light sense fades gradually towards the periphery. Again, the scotopic eye is colour blind, but on the admission of more light the first colours recognised are yellow and blue, after them the greens, and, finally, the reds. On a dark night the grass looks grey, while the colour of yellow flowers may still be distinguished, but the red geraniums appear black. As there are no rods in the fovea, though they are found in increasing numbers towards the periphery, it will be seen that there are some good *prima facie* grounds for considering the rods as the percipient elements for light sense and the cones for colour sense.

The light sense may be tested in two different ways: (1) Light difference (L.D.): The estimation of the smallest difference of brightness that can be appreciated between two sources of nearly equal luminosity; and (2) light minimum (L.M.): the estimation of the smallest quantity of light that can be recognised in a faintly illuminated patch on a black background. Ophthalmologists find that L.D. is most affected in diseases of the optic nerve, but that L.M. is chiefly diminished in glaucoma and in diseases of the retina and choroid. It is found that practice increases the L.D. sensibility enormously, and, indeed, the results of L.D. and L.M. tests vary so greatly in different individuals that no definite value can be assigned as the standard of either. When Professor E. M. Barnard (Yerkes Observatory, U.S.A.) found that he could detect a wire at such a distance that its diameter only subtended an angle of  $0.44''$  (i.e., less than half a second) at the nodal point of his eye, it is a proof of his extraordinary sensibility to light difference; it is no test of his form sense.

The minimum visible for form sense is  $53.1''$ , and is usually taken to be  $1'$ . Many tests that are supposed to deal with the form sense are really only testing L.D. Even the dot test cards that are so frequently used fall under suspicion for this reason. In practice this may not be very serious, as in many callings an adequate light sensibility is more important than a superior form sense. On a dark night most people have found that they see better without their spectacles than with them, as then they are relying upon their light sense and not upon their form sense, which is improved by increased definition. Every optical instrument entails some loss of light from absorption and from reflection at the surfaces of the glass; and yet, as is well known, telescopes enable one to see stars that are invisible to the naked eye, and night glasses are of invaluable use to the mariner. The principles underlying these two instruments are entirely different.

The apparent brightness of a surface in ordinary circumstances, if the size of the pupil remain constant, simply depends upon the intrinsic brightness of the surface. A piece of white paper 1 in. square at a distance of 4 ft. is as bright as a piece 1 ft. square. If, however, an object be so small that its image only falls on part of a bacillary element, unless it be exceedingly bright it may not succeed in stimulating this element. When faint stars are observed through a telescope their apparent size is not increased, for they still subtend an angle less than the minimum visible, but all the light which falls on the object glass may by a suitable eye-piece be concentrated on the observer's pupil, neglecting the light lost by transmission through the instrument. The action of the telescope is tantamount to increasing the area of the pupil to that of the object glass, and hence the brightness of the faint star is virtually increased. If, however, the object viewed subtend an angle (e.g.,  $10'$ ) greater than the minimum visible, no optical instrument can increase its brightness per unit area. Yet, as is well known, in the dusk a night-glass enables objects to be seen that are invisible to the naked eye, although telescopes with a magnification of 20 or so will prevent objects being seen that can be dimly distinguished without it. Similarly, all microscopists have noted that when high eye-pieces are used the field becomes much darker. This is simply because the emergent beam of light from a high ocular is so thin that only part of the pupil is filled with light; indeed, the pupil receives far less light than when a lower eye-piece is used. Now one advantage of a Galilean binocular is that the section of the emergent beam is never less than that of the pupil and, consequently, no light is lost from this cause. But we have said that the brightness per unit area cannot be increased, how then can the visibility of an object in a dim light be increased by night-glasses? All workers agree that the minimum intrinsic brightness necessary for the perception of an object varies greatly with its size. It is clear, then, that night-glasses with a magnification of 4 or 6 will increase the visibility of objects in a dim light owing to their increased apparent size. We may at once conclude that as long as the section of the emergent beam is not less than the pupil of the observer's eye advantage will be gained by increasing the magnification; but if the sectional area of the emergent beam is less than that of the pupil the image may become even

dimmer than the object when seen by the naked eye. Piper<sup>1</sup> has pointed out that in dark-adapted eyes the light sensibility is about twice as great with both eyes as with one, though in light-adapted eyes no such binocular summation takes place.

#### THE BRITISH SCIENTIFIC PRODUCTS EXHIBITION.

UNDER the auspices of the British Science Guild a very interesting exhibition of British scientific productions was opened by Lord Crewe at the Central Hall, Westminster, on Thursday, July 3rd. Encouraged by the success which attended a similar exhibition held last year at King's College, the authorities were amply justified in promoting another exhibition this year, the objects of which are to illustrate recent progress in British science and invention, and to help the establishment and development of new British industries. The demonstration is most instructive, and evidences in many directions the capacity and skill of the British manufacturer in acquiring new industries and in restoring old ones on a scientific basis. There is, indeed, a wealth of products shown, illustrating in the most satisfactory way a determination to press science into industrial service and to remove the long-standing reproach of our dependence on other nations for the supply of many valuable and important commodities. And there is a noble record presented of the work done in the research laboratories of the universities and schools of England. All is an eloquent story of the successes gained by the men trained in the scientific and technical laboratories. Mechanical science, physics, textiles, electrical appliances, medicine and surgery, paper and illustration, agriculture, chemistry, aircraft, fuels, and metallurgy form most interesting sections, in which examples are numerous enough of the talent, skill, and energy not yet lost to our race. Synthetics and dyes are conspicuous illustrations of recent commercial successes resting on scientific foundations, and the exhibition of optical glass and laboratory glass ware demonstrates a brilliant dual triumph of scientist and manufacturer. The great drug houses are well represented, showing what an essential equipment to the success of their business is the research laboratory. This opportunity of witnessing the remarkable developments arising out of the events of the war which have taken place in so many departments of our great industries should not be lost. The bearing of science upon industrial success and national prosperity is well brought out. The exhibition continues until August 5th.

#### THE MEDICAL AND DENTAL REGISTERS.

THE official Register of the General Medical Council, which has just been issued, contains the names of 43,926 persons, of whom 54 per cent. are on the local Register for England, 32 per cent. on that for Scotland, and 14 for Ireland. 1077 names were registered in 1918, being the smallest number recorded for a quarter of a century except at the low tide of 1910-11. On the other hand, the net increase of 107 registered names at the end of 1918 as compared with 1917 is quite without precedent in its smallness. The previously leanest years had some compensation, lacking in 1918, in names restored to the Register and short death rolls. The additional names registered during 1918 included 148 colonial and 16 foreign

diplomats, for the most part Belgian. 995 names have been removed from the Register during the year, 946 on evidence of death. Only one medical man has formally removed his name from the list as having ceased to practise.

The official Dentists Register for 1919 contains the names of 5567 dentists, of whom 13 are on the colonial and 19 on the foreign list. Of the 5535 United Kingdom dentists, 4290 hold degrees or licences in dental surgery, and 1245 are registered on their own declaration of being in bona-fide practice of dentistry. Of the former, 461 have additional surgical or medical qualifications, of the latter 7. The number added by registration during the year 1918 was 131, being one in excess of the figure for 1917 and barely one-half of the 1915 record. 102 names were removed on evidence of death, none on ceasing to practise.

#### EPIDEMIC ENCEPHALITIS (NONA).

A USEFUL contribution<sup>1</sup> to the subject of epidemic encephalitis, from the pen of Dr. Peter Bassoe, associate professor of medicine, Rush Medical College, Chicago, shows that the disease has made its appearance in America, with similar clinical and pathological features to those frequently described in this country and on the continent. Sainton has attempted to give a definition of the disease in the following terms: "A toxic, infective, epidemic syndrome, characterised clinically by the triad lethargy, ocular palsies, and a febrile state, and anatomically by a more or less diffuse encephalitis, most marked in the grey matter of the midbrain." It may be questioned, however, whether any useful purpose is served at present by condensed definitions; Sainton's is not sufficiently explicit to be distinctive. The association of epidemic encephalitis with influenza appears to be more than a mere coincidence, since it has been noted on a number of occasions. Dr. Bassoe quotes from a French source that Camerarius, who described an influenza epidemic in Tübingen in 1718, mentioned a "sleeping sickness" in connexion with it. In 1768, Lepeque de la Cloture recorded a "coma somnolentum" after influenza, and Ozanann (1835) mentioned epidemics of "catarrhal fever" with "soporosité" as having occurred in Germany in 1745, in Lyons in 1800, and in Milan in 1802. No doubt much of this is vague and indeterminate; influenzal meningitis is a different affection altogether, and what (much or little) of these epidemic conditions should be classed as encephalitis lethargica is a matter depending really on the interpretative proclivities of the reader. Dr. Bassoe describes 11 cases in his paper, and notes that in no one had there been definite preceding influenza, but suggests that the encephalitis "may be caused by a separate virus, which in order to become active must have been in contact at one time or another with that of influenza." Be this as it may, the bacteriological aspect of the question has been less completely investigated than the clinical and pathological, and has scarcely passed the stage of conjecture. It is an interesting observation that the brain-stem and basal ganglia are particularly liable to be affected by poisonous, endogenous or exogenous, though why this should be so is not at present clear. Dr. Bassoe has had the opportunity of making a complete pathological examination in two cases, and has found the changes with which previous writers

<sup>1</sup> Ztsch. f. Psychol. u. Physiol. d. Sinnesorg., xxxii., 98., 1904.

<sup>1</sup> Journal of the American Med. Assoc., April 5th, 1919, p. 971.

have made us familiar—œdema, congestion and minute hæmorrhages, these most numerous in brain-stem, basal ganglia, and centrum ovale, dense accumulations of small cells round the vessels, and comparatively little evidence of necrosis or tissue destruction. In his cases there was but little sign of inflammation in cortex or meninges. He makes the interesting remark that there is not so much real sleep as is indicated by the sleepy expression of the patient; in fact, some actually suffer from insomnia, "lethargy" bearing the same relation to sleep as the compulsive laughter of the patient with pseudo-bulbar paralysis does to a normal laugh. Among other clinical features also observed in various English cases may be specified coarse choreiform jerks, which sometimes have become very troublesome, and which Dr. Bassoe has been able to control temporarily with scopolamine. There is much more evidence than the casual observer would suspect to support the contention that the lethargy of these patients is a local and not a general symptom. The laboratory tests of the spinal fluid in Dr. Bassoe's 11 cases show that the cell content was less than 10 in the majority, with a maximum of 26; the fluid was always clear, and usually gave a slight increase of globulin. Results of cultures of blood and spinal fluid, both during life and after death, were negative. No bacteria were seen in section of the brain.

#### SIR CLIFFORD ALLBUTT'S PORTRAIT.

THE fund for presenting the President of the British Medical Association with his portrait remains open by request during the present month. Subscriptions have recently been received from India and America. The treasurer, Dr. G. E. Haslip, in a letter which appears in our correspondence columns, invites all those who wish to take part in the presentation, but who have not yet notified their intention, to do so without delay. After the portrait in oils has been painted it is intended to commission a mezzotint engraving from it, which subscribers to the fund will be able to purchase for their own collections.

#### RABID IGNORANCE.

THE worst kind of ignorance is that which springs from an instinctive refusal to acknowledge the truth. The Arabs long ago recognised how obstinate and intractable is this affliction when they said: "He that knows not, and knows not that he knows not, is stupid. Shun him." To argue with such people is clearly waste of time, for no amount of reason can prevail against a well-established complex. But to ignore the victims entirely would be as foolish as merely to avoid the company of a dangerous criminal. Indeed, if the definition of crime be a fairly broad one, such people are dangerous criminals, for, as Dr. Johnson says: "He that voluntarily continues ignorant is guilty of all the crimes that ignorance produces." The stamping out of rabies in this country 30 years ago was carried through in the face of violent and prejudiced opposition. It could hardly be expected that the arguments then used against the Muzzling Order of 1885 should be brought forward again to-day. Yet such does actually appear to be the case. At a recent meeting of the Animal Defence and Antivivisection Society (in the words of its secretary) strong feeling was expressed at the unscrupulous way in which the present scare is being worked

up. "To prevent rabies in dogs," he writes "it is essential that they should be well and carefully fed, given plenty of water, enough exercise, and not kept in the sun." By such well-meaning people the currency of truth is debased and it becomes important that the real nature of rabies and hydrophobia should be placed before the public by competent authorities in order that such misleading statements as that quoted above may be recognised at their true value. The Society for the Prevention of Hydrophobia, founded in 1886, is still, we are glad to say, in existence, and their first secretary, Mr. Frank Karslake, has rendered a valuable service in reissuing his pamphlet first published in 1889.<sup>1</sup> The arguments used in it remain as true to-day as they were at that time, and various additions have been made which bring them into more intimate contact with the world of to-day. May it have a wide circulation amongst the open-minded public, for it is a valuable prophylactic against the views of those who know not that they know not and are still at large. More than 200 cases of rabies have now been confirmed, and recent reports show that the disease is by no means arrested, a new outbreak having occurred this week. Dr. Addison, speaking last week on a vote to liquidate the Local Government Board, stated that 54 notifications had been received of persons bitten by rabid dogs, and of these 19 were sent to Paris for antirabic treatment; 24 were treated in England with vaccine obtained from the Pasteur Institute in Paris, and 11 others with vaccine prepared in the Board's own laboratory. In no case had hydrophobia resulted, and this admirable achievement of preventive medicine has been used by unscrupulous persons to suggest that no need for any treatment exists. Those who have been saved from the risk of a painful and horrible death will think otherwise, and the public meeting held last week in London under the auspices of the Kennel Club was unanimous in recommending the common-sense measure of a general Muzzling Order throughout the country. The Board of Agriculture may be assured of the support of well-informed public opinion in enforcing whatever regulations may be found to be necessary once again to deliver from this curse both man and his most faithful beast.

#### THE PATHOGENESIS OF DEFICIENCY DISEASE.

A VERY interesting contribution to the literature of this subject has recently been made by Lieutenant-Colonel R. McCarrison, I.M.S., of the Pasteur Institute of Southern India, in the *Indian Journal of Medical Research* (vol. vi., No. 3), in which he discusses the origin of diseases attributed to a deficiency of certain accessory food factors. He draws attention to the scantiness of our knowledge respecting the influence of "vitaminic" deficiency on the adrenal glands, pancreas, liver, spleen, thyroid, pituitary gland, and the reproductive organs, and he endeavours to fill up some of these gaps in our knowledge. Taking beri-beri as the typical deficiency disease, he expresses the opinion that "vitaminic" deficiency is the essential ætiological factor in the genesis of that malady, but that such deficiency is rarely so complete as to be the sole agency responsible for it. Bacterial organisms of whatever kind that may be isolated from the blood in human beri-beri may invade the blood and tissues under conditions of dietetic

<sup>1</sup> Rabies and Hydrophobia: their Cause and Prevention, by Frank Karslake. London: W. and G. Foyle, 1913. Price 1s.

deficiency and thus convert a state of potential morbidity into one of kinetic disease. Such organisms are not the cause of the malady, nor can they be expected to produce it in inoculation experiments. "They are but weeds which flourish in a soil made ready for them by dietetic deficiency." After making many animal experiments and observations Colonel McCarrison arrives at the conclusion that the absence of certain accessory food factors from the dietary—improperly called "anti-neuritic"—leads not only to functional degenerative changes in the central nervous system, but to similar changes in every organ and tissue in the body. The symptom-complex resulting from the absence of these substances is due (1) to chronic inanition; (2) to derangement of function of the organs of digestion and assimilation; (3) to disordered endocrine function, especially in the adrenal glands; and (4) to malnutrition of the nervous system. Certain organs undergo hypertrophy and others atrophy. Those which hypertrophy are the adrenals, and those which atrophy are, in the order of severity, the thymus, the testicles, spleen, ovary, pancreas, heart, liver, kidneys, stomach, thyroid, and brain. The presence of œdema in the patient has been invariably associated with great hypertrophy of the adrenal glands. Wet and dry beri-beri are essentially the same disease, the former differing from the latter in the greater derangement of the adrenal glands. Gastric, intestinal, and pancreatic disorders are important consequences of a dietary too rich in starch and too poor in vitamins and the essential constituents of food. It is suggested that some of the obscure metabolic disorders of childhood might be examined from this point of view as well as from that of endocrine gland starvation. Profound atrophy of the reproductive organs is also an important consequence of vitaminic deficiency, leading to the cessation of the function of spermatogenesis. In the male human subject it would result in sterility, and in the female in amenorrhœa and sterility. This would no doubt account in a great measure for the recent occurrence of so-called "war amenorrhœa," about which much has been written recently in the foreign press, and particularly in Germany. The central nervous system atrophies little, the paralytic symptoms in beri-beri being due mainly to impaired functional activity of nerve cells, much more rarely to their degeneration. It is thought that because of their atrophy, out of all proportion to other tissues, the thymus, testicles, ovary, and spleen provide a reserve of accessory food factors for use on occasion of metabolic stress, but this reserve is rapidly exhausted. Finally, although deficiency of certain accessory food factors is the essential ætiological factor in the genesis of beri-beri, Colonel McCarrison holds that infectious and parasitic agencies may often be important causes determining the onset of the symptoms of that disease. Vitaminic deficiency renders the body very liable to be overrun by the rank growth of bacteria, and it is probable that varying metabolic disturbances may determine the character of these growths. We are glad to learn that Colonel McCarrison proposes to continue his investigations on this most interesting subject, and that he promises shortly another contribution dealing with the effects of a deficiency of accessory food factors on the function of the thyroid gland, with a histological study of 69 pairs of thyroids removed in the course of his experiments on pigeons and other animals fed on a polished rice dietary.

## NATIONAL CONFERENCE ON INFANT WELFARE.

COMMENCING on July 1st, the League for Health, Maternity, and Child Welfare held at the Kingsway Hall a three days' conference, in which child welfare in all its aspects was discussed. The proceedings were opened on the first day by Dr. CHRISTOPHER ADDISON, M.P., who outlined the objects of the conference.

The first paper was read by Dr. AMAND ROUTH (consulting obstetric physician to Charing Cross Hospital) and was entitled—

### *Causes of Antenatal, Natal, and Neonatal Mortality.*

He said that the conference would that day discuss how to save the lives and ensure the health of babies, considering the question from the very beginning of life, from the moment of fertilisation to the end of the first month after birth. The natural increase of the population had for the first time in our statistical history ceased, for during the six months ending March 31st last the deaths in England and Wales had exceeded the births by 126,445. The approximate percentage causation of antenatal, natal, and neonatal deaths could be given as follows with fair accuracy: prematurity, 10 per cent.; syphilis, 20 per cent.; toxæmia, 10 per cent.; prolonged, difficult, or complicated labour, including antepartum hæmorrhage, 25 per cent.; other known causes, 10 per cent.; and "unknown" causes, 25 per cent. The fact that so large a percentage of the causes of antenatal death was "unknown" showed how much research and pathological team-work was still required.

The following table gives an estimate of the probable loss of life between fertilisation of the ovum and the end of the first year of life:—

*Antenatal and Infantile Death-rates per 1000 Births of Children of Married and Unmarried Women, including "Natal" Deaths, Based on the Figures for England and Wales in 1917.*

	Married.	Unmarried.
Antenatal.		
In latter 12 weeks ... ..	30 } = 150	60 } = 300
In former 28 weeks (estimated) ... ..	120 }	240 }
Infantile.		
Neonatal (first month) ... ..	37 } = 96	72 } = 207
Remainder of first year ... ..	59 }	135 }
Estimated deaths of children per 1000 births between conception and end of first year of life.	246	507

Note.—The actual deaths of mothers per 1000 births from causes connected with pregnancy and labour were: Married, 3.7; unmarried, 6.79.

It was evident, therefore, that the unmarried mother and her child needed the care of the State twice as much as the married woman if they were to be saved from this double rate of mortality and morbidity.

At the conference held last year Dr. J. W. Ballantyne wisely advised that the labour group of cases should be called distinctively "natal" or "intranatal," and he further suggested that the mortality of this period should be considered separately, for not only does it include all the operations needed to save the child in cases where there is a disproportion between the child and the maternal pelvis, but all the other complications of childbirth, such as maternal hæmorrhage, pelvic tumours, foetal malpresentations, and pressure on the umbilical cord. Many malnourished, diseased, malformed, and premature children who fail to survive their birth would also belong to this group.

At the same meeting of the conference Dr. Ballantyne suggested that the first month after labour should be designated "neonatal," and the phrase is now generally adopted. It is known that the deaths of this neonatal period include 37 per 1000 births of the children of married mothers, and 72 per 1000 births of unmarried mothers, or about a third of those who die in their first year of life. These early infantile deaths comprise (1) feeble, malnourished or premature children who survive their births, 50 per cent. of whom die in the first 24 hours of life; (2) diseased children, such as those born syphilitic; (3) abnormal or deformed children, such as those born with hydrocephalus, spina bifida, ventral hernia, or encephalocele; (4) many children who may survive some weeks but who cannot suck owing to prematurity, cleft palate, hare-lip, or "snuffles." This "neonatal" period not only includes the risks to the premature or diseased child which occur in the

first few days of life, but also includes a period when the obstetrician (medical practitioner or midwife) has ceased to attend and the pediatrician or infant-welfare doctor takes on the case of the child, while the gynaecologist perhaps is required for the mother.

Premature births are so called if they occur before the thirty-eighth week of gestation. The causation of prematurity has not been satisfactorily worked out, but is often due to antepartum hæmorrhage, toxæmia, or undue physical effort or mental strain in the mother, or to malnutrition or morbidity in the child, which conditions should be therefore viewed as the primary causes of the foetal death rather than the resulting prematurity at birth.

Amongst the main causes of death in both early and late pregnancy is venereal disease. Gonorrhœa is very rarely the cause of antenatal disease or death. Syphilis is estimated to cause at least 20 per cent. of the antenatal and neonatal deaths, and, if so, it would mean that about 27,000 deaths would thus result in England and Wales.<sup>1</sup> Stillbirths from antenatal syphilis in unmarried women are about double such deaths in legitimate pregnancies. Maternal toxæmia causes from 10 to 15 per cent. of foetal deaths. These toxæmias are said to occur in 5 per cent. of primigravidae, and are still more frequent in unmarried women who have to endure much more mental strain during their pregnancies. Accidents and complications of childbirth constitute the largest group of antenatal and neonatal deaths. Pelvic contractions, or tumours, or foetal malpresentations are not only dangerous to the mother if the condition is recognised first during labour, but are still more dangerous to the child, who may have to be sacrificed to save the mother, for obviously if the mother cannot be delivered the mother and child would die. Maternal hæmorrhages, such as those due to placenta prævia and accidental hæmorrhage, especially the concealed variety, are the most fatal of all complications if not treated promptly. There are other occasional maternal causes of foetal disease or death which could often be successfully treated if detected during pregnancy. He would only mention heart disease, Bright's disease, lead poisoning, malignant disease, acute specific exanthemata, pneumonia, and other acute and chronic lung conditions.

Dr. EARDLEY HOLLAND then read a paper on the Results to be Expected from Antenatal Care, which we print in full in another column.

Dr. J. J. BUCHAN (medical officer of health, Bradford) followed on the subject of

#### *Antenatal and Neonatal Mortality.*

He said: All those who have followed closely during the past 20 years the campaign in this country for the reduction of infantile mortality will have been struck with the varying phases of the movement and the great number of subjects investigated in relation to it. We have learned much in this time of the many factors that influence the health of the infant after birth and much good work has been done to reduce infantile mortality in the later months of the first year of life, but the field of knowledge of the conditions before birth affecting the welfare of the child when born is almost unbroken. We have hardly any accurate facts of antenatal or neonatal mortality; we cannot state with any degree of reasonable certainty the extent, the causes, or the steps to be taken to effect a reduction.

From the published figures of the Registrar-General it would seem clear that about 12 per cent. of the infantile mortality occurs before the infant is a day old and about 25 per cent. before it is a week old, and from 35 to 40 per cent. before it is a month old. If to these babies born living who died almost immediately the babies born dead are added, the number of deaths due to antenatal and neonatal causes is large indeed.

It would be well, without going further, to insist for the moment on the importance of increasing our avenues of knowledge so that these deaths may be more carefully investigated. Stillbirths are not recognised by the law for registration purposes, a great many do not come under the Notification of Births Act, and without doubt numerous others which should come under this Act escape notification. The blind position of the law, which only recognises life as commencing after birth, is responsible to a great extent for the lesser importance with which these births are regarded, and while from its own point of view the legal

position is a reasonable one some means should be devised to bring all stillbirths and miscarriages, certainly after quickening, before the notice of the health authority in the interests of infant life. The Notification of Births Act requires the notification of a stillbirth occurring after the twenty-eighth week of pregnancy. Anyone who has followed the administration of the Midwives Act will be struck by the apparently small proportion of stillbirths notified by midwives. This arises chiefly from the fact that stillbirths in midwives' cases occur largely among those cases for which they seek medical aid, so that the stillbirth is ultimately notified by the doctor and not by the midwife. Thus, in Bradford during the past three years, while the general rate of stillbirths notified was 4.6 per cent. of the births notified, the stillbirth-rate among doctors' notifications was 6.4 and among midwives' notifications 3.2 per cent. of births notified.

The causes of these deaths can be classified in two groups, those arising during the actual labour and those arising or existing during the pregnancy. Every improvement in the midwifery service of the country will tend to lessen materially the deaths arising from neonatal causes, but we have not yet seen any very vast improvement in the midwifery service of the country generally. Though the Midwives Act has now been in operation for many years, its full benefits are still to be enjoyed by the community, as the bona fide midwives still carry on large practices, and the general service of midwifery is not attracting those recently and well-trained women whose names have swelled the Midwives' Roll. In the towns of the North of England there is an average of 70 per cent. of the births attended by midwives, rising in some cases to over 90 per cent. The work these women are doing is of paramount importance to the mother and the child and to the whole community, and it is of the utmost importance that their ranks should be recruited from the best women trained in practical midwifery. In years gone by the inefficiency of particular midwives has been tolerated, especially in some of the worst districts of our large cities and towns, by the knowledge that if this inefficient midwife did not practise there no one else would. She was practising for a mere pittance, irregularly received, and she served to meet—badly as she did it—a public want.

Since the passing of the National Insurance Act, with the inauguration of maternity benefit, such circumstances have not been so frequent, but nevertheless I am afraid that in many districts they still do exist. A consideration of such circumstances as these has led to the inauguration of the municipal midwife, whose advent will probably do more for antenatal and neonatal mortality than has yet been done. At present, in the City of Bradford, we have 12 municipal midwives who are attending more than half the births attended by midwives in the city. Antenatal work has been constantly talked of these last few years but very little has been done anywhere. It is amazingly difficult work to develop; it is easy to start an antenatal centre and to set aside hours for consultation and the like, but this is not sufficient. Much has to be done to educate women as to the need for antenatal supervision and care, but I do not think that this is best, if at all, attained by a notification of pregnancy and the appearance of another supervisor of their health apart from their midwives and their doctors. It is necessary to enlist especially the midwife in the service of the antenatal authority. The midwife has been sought out by the expectant mother herself, and will have much more influence with her than anyone else. Midwives themselves have to be taught to appreciate the meaning and the importance of antenatal work, and they have to impress upon their clientèle the need for early booking of their confinement. The municipal midwife is required to see her patient very frequently before the birth and to seek the aid of the antenatal clinic on all occasions. A definite antenatal centre, though of very great importance in antenatal work, is relatively of less importance than a well-organised and educated midwifery service. Without such a service the work of the centre is set at naught. We have been feeling our way for the past few years to antenatal work, but as a result of experience I think it can be said that it is not much use to establish antenatal centres without sufficient means of getting into touch with the work to be done. Antenatal centres must work in close association with hospital accommodation for gynaecological and maternity cases, and they have to establish a very intimate coöperation with the means of treatment for venereal disease.

<sup>1</sup> THE LANCET, 1918, I., 45.

Miss OLIVE HAYDON (formerly sister, York-road Lying-in Hospital), in the absence of Dr. VERA FOLEY, then gave the conference the benefit of her experiences on the subject of

*The Work of the Midwife in Relation to Antenatal and Neonatal Mortality.*

The speaker began by emphasising: 1. The need of educating women in hygiene and mothercraft. 2. The high mortality during intra- and extra-uterine life due to preventable illness, and the insidiousness of the manifestations of diseases, such as syphilis, gonorrhoea, and the toxemias of pregnancy. 3. The need for further research work into the cause of ante- and neo-natal mortality. 4. The difficulty of bearing and rearing healthy children in poverty-stricken homes by unfit parents.

Midwives, she went on, besides practising independently and as staff midwives in institutions, are working under medical supervision as health visitors, creche nurses, rescue workers, infant welfare superintendents. Personally, I think every midwife, when qualified, should practise her profession for at least a year before taking up other work. This would lead to a broader and more sympathetic attitude to those who are practising midwives. To do more efficient work the midwife needs progressive education on broad lines, better economic conditions that will allow her to take fewer cases, and devote full attention to each patient she attends—and a status and consideration commensurate with the importance of her work for maternity and child welfare.

In conclusion, Miss Haydon touched on the midwife's work *vis-à-vis* with the patient. It is, she said, mainly threefold—educative, preventive, and practical—and of these three perhaps the most important is the education of the expectant mother, the mother, and the baby. The education begins at booking; unfortunately, this is seldom before the sixth month. Much writing has already been done on what Professor Thomson has called "the docket" of the new-born child, and much is irremediable. But the normal rapid growth and development of a normal foetus may be retarded or interrupted by the ill-health or excesses of the mother during the last three months; hence the need for forewarning help and continued careful observation for abnormal signs and symptoms, so as to secure early medical treatment for physiological breakdown or infection. The former history, the general condition, and the physical examination of the patient should guide the midwife in dealing with the patient and help her to form an opinion as to whether it is advisable in the interests of the mother and unborn child to be attended by her. The midwife will receive with caution and some inward scepticism the explanation of the causes of previous miscarriages; she knows that thousands are attributed to shocks and falls, a very few to albuminuria, syphilis, &c., and still fewer to the taking of noxious drugs and drastic purges. She ought not to be content that a series of miscarriages should be attributed to those refuges of the destitute "habit" and "a weak inside." She may even dare to inspire with optimism the woman who has been told she would never carry a child to full term. The careful examination of the breasts and nipples begins the education on the value of breast-feeding; careful investigation into the causes that led to its abandonment with previous children forewarn and forearm the midwife. If it has been given up because the mother has had to go to work, there is always hope that she may be convinced that her primary duty is not washing or charring, or any other work in the labour market, but the persistence in breast-feeding. With an eight-hourly working day, and four-hourly feeding, there should now be fewer children fed from tins or poisoned slowly with contaminated milk, deprived of its accessory growth products by sterilisation.

The midwife is shrewd enough to know that faulty mothercraft, poverty, the health and character of the parents, bad hygienic surroundings are far greater factors in antenatal and neonatal mortality than hard work, smoke-laden atmosphere, bad midwifery, or even those plagues of the midwife's life—the "born before arrivals." A midwife's judgment of the character and capacity of the mother and home life is by no means to be despised; she has unique opportunities of studying these in her repeated and welcomed visits to the home.

Miss M. BURNSIDE, O.B.E., inspector of midwives and county health visitor, Hertfordshire County Council, then spoke on the work of the midwife in relation to antenatal and neonatal mortality in rural districts.

The afternoon session on July 2nd was given up to a discussion on Industrial Employment of Mothers in Relation to Infant Mortality, when the speakers were Dr. Rhoda Adamson, clinical lecturer in obstetrics at the University of Leeds, Miss L. Barker, of the Training Department, Ministry of Labour, and Mrs. Holden, of Dewsbury. Both sessions on July 3rd were occupied in discussing the subject of the Unmarried Mother and the Unwanted Child.

## AMERICAN MEDICAL ASSOCIATION : ANNUAL MEETING.

THE Seventieth Annual Meeting of the American Medical Association was held in Atlantic City from June 9th to 13th. The first day was taken up with business matters by the House of Delegates.

### *Report on Medical Education.*

Among other questions of interest Dr. JOHN A. DODSON, of Chicago, submitted the report of the Council on Medical Education. A fact in this report worthy of emphasis was that of the 20,678 students who graduated during the past six years 15,025, or 72.6 per cent., were admitted under the higher entrance requirements, and received their training in the Class A medical schools.

### *Report on Social Insurance.*

Dr. ALEXANDER LAMBERT, of New York, submitted the supplementary report of the subcommittee on social insurance. He stated that during the years 1915, 1916, and 1917 the committee had inquired extensively into the question of whether there was a sickness problem, what it was, and how it was to be met. The findings were that 2.6 per cent. of the population were seriously sick all the time, 1.5 per cent. were more or less disabled, and that among the 38,000,000 employees in the United States there was an average of nine days' illness per man per year. In figures about \$500,000,000 (£100,000,000) a year would represent the loss in wages by the wage-earners from sickness. The amount of sickness in a family was found to vary inversely as the wages of the family; also the sickness rate was higher in proportion as the number in the family increased. In well-to-do families the infant mortality-rate in America averaged 41 per 1000 births, while among the poor it averaged 225 per 1000 births. Only 25 per cent. of pregnant women received anything like adequate antenatal care. In Philadelphia 60 per cent. of the sick poor had only home care, and patent medicines were found to be used by from 25 to 50 per cent. of these persons. In about 35 per cent. of the cases the wage-earners had sickness insurance amounting to 10 or 15 per cent. of the wages; some carried a voluntary insurance, but the larger proportion had no insurance at all against sickness.

The report considered the question of sickness insurance, and after pointing out that general insurance schemes in Germany and England had not been found to work well, the opinion was stated that a solution must be found through the organised aid of the medical profession with the help of the State and county medical societies. The medical profession should decide whether better protection against sickness could be obtained through the increase of State Health Department control, or whether it should be sought, as in England, through a *pro rata* per man per year fund.

### *Distinguished Guests.*

The meeting proper began on Tuesday, June 10th. A feature of the meeting was the presence of a number of foreign guests. Among these were Mr. Ernest W. Hey Groves, Sir StClair Thomson, Major-General Sir Bertrand Dawson, Sir Shirley Murphy, Sir W. Arbuthnot Lane, Sir Arthur Newsholme, Colonel Sir W. T. Lister, and others, including representatives from France, Belgium, Greece, Norway, Sweden, Cuba, and Japan.

### *The Presidential Address.*

Dr. ALEXANDER LAMBERT, the President-elect, delivered the presidential address on Medicine, a Determining Factor in War. He pointed out the success of preventive medicine in the war just over. As for the lessons learned in determining action in future, Dr. Lambert thought that the experience of the last war and the history of recent wars had shown clearly that only through proper

representation on the general staff of armies by those men trained in the methods of salvage and by experts in sanitation could these duties be efficiently performed. The final paragraph of the address discussed the national control of preventable diseases. The war had taught that there remained economic value in the maimed and wounded, and it was the duty of the State to develop this value to the fullest extent. The maiming and injury of workers in the everyday work of industry far exceeded each year the battle casualties of this war, and there was an economic necessity and duty to be performed in the salvage and reconstruction of the industrially injured. The President ended an eloquent address by urging that it was the duty of the American Medical Association and of each member of each State association to press on Congress the need for the establishment of a National Department of Health.

#### *Health of the United States Navy.*

At the meeting which was held on the evening of Wednesday, June 11th, national organisations, the activities of each of which have a definite medical interest, were represented by speakers chosen by these organisations. Among these speakers was Commandant JAMES R. PHELPS, U.S.A., who spoke as the representative of Surgeon-General Braisted. He said that the death-rate for the first year of the war in the United States Navy was lower than for the previous year of peace. The rate was 8.8 per 1000, the lowest ever reached by the naval or military service at war.

#### *The Public Health Service.*

Dr. C. C. PIERCE, of the United States Public Health Service, spoke as the representative of Surgeon-General Blue, and outlined briefly the activities of the Public Health Service in connexion with the war.

#### *The American College of Surgeons.*

Dr. FRANKLIN MARTIN, as the representative of the American College of Surgeons, spoke of the organisation of that body, which had been patterned after the Royal College of Surgeons of England. They had now a membership of 4000 in the United States and 400 in Canada.

#### *War Surgery and the Surgery of Civil Life.*

In the Section of Surgery, General and Abdominal, Dr. JOHN J. BOTTOMLEY, of Boston, the chairman, discussed briefly the influence of the surgery of the great war on the surgery of civil life. He pointed out that no entirely new surgical principle was discovered during the war, but in this fact there was no discredit to surgery since the long-established principles upon which it rested had emerged triumphant from a tremendous test. At no period of the war were the principles of asepsis and antisepsis in danger; their practice, however, was at first rudely shaken because of the novelty of military conditions. Dr. Bottomley then dealt with the accomplishments of recent military surgery in their relation to civil practice. It had been demonstrated, he said, that even in severe wounds, with existing contamination, infection could be prevented or controlled. Tetanus had practically been banished because of the preventive property of the antitoxin. Treatment by magnesium sulphate and carbolic acid had been definitely put aside. The wound conditions favouring the development of gas gangrene were recognised, its pathology was known, and the earliest signs of its presence were tabulated, and consequently its treatment was now on a more scientific and successful basis. There were promising indications that an effective antitoxin for it might be developed. There was no longer any question as to the proper treatment either in peace or war of penetrating wounds of the abdomen. The contention of the civilian surgeon had been upheld. Many of our doubts as to chest surgery had been dispelled. The need for complicated pressure apparatus had gone with the establishment of the fact that without it the pleural cavity might be opened freely and the lung handled without special danger. Convincing evidence had established beyond doubt the position of those who in pre-war days asserted that synovial membrane had strong powers of resistance to infection, and that drainage of joints recently wounded was not only unnecessary but often harmful. The factors entering into the production of shock and the details of its treatment had been so vividly delineated that no surgeon who had to do with the great industries in which severe injuries were common could afford to neglect provision for the prompt and efficacious treatment of the shock that might accompany them. The treatment of

fractures had been stabilised by the standardisation of splints and other apparatus for immobilisation, which had largely supplanted the use of plaster-of-Paris.

#### *Influenza in the A. E. F.*

Among the instructive papers read was one surveying the epidemic of influenza in the American Expeditionary Force, by Dr. WARFIELD I. LONGCOPE, of New York.

#### *Malaria Treated by Disinfection.*

Another paper which attracted a good deal of attention was that by Dr. C. C. BASS, of New Orleans, dealing with the effective and practical treatment of malaria by disinfecting infected persons. From 50 to 68 per cent. of the malaria occurring in a representative malarial locality of the United States was relapse and not new infection. The chief cause of ineffective treatment was the employment of spectacular and unpractical methods. The discomfort and inconvenience of quinine in solution was referred to as an example of improper and unpractical methods of treatment. Blood examination could not be depended upon to determine when disinfection had been accomplished. The only trustworthy guide was the length of time proper quinine treatment had been kept up. An effective method of treatment was to administer ten grains of quinine sulphate every night before retiring for a period of eight weeks. This was effective in about 90 per cent. of cases.

#### *War Hysteria.*

In the Section on Nervous and Mental Diseases Dr. TOM A. WILLIAMS, of Washington, D.C., read a paper on the Management of War Hysteria. He said that most patients could be restored immediately if skilfully treated, but differentiation must be made between cerebral commotion and chronic emotivity. Cardiac fatigue in hysterical subjects often suggested the long-continued incapacity which might manifest itself as an effort syndrome. In a majority of cases collective suggestion was an important feature of treatment, but in a more complex case individual analysis was essential. The methods most generally and successfully used had been: 1. Direct suggestion in the early stages at the front. 2. Indirect suggestion and persuasion, often combined with torpor or other uncomfortable applications or by isolation. 3. Best of all, however, a metamorphosis of the patient's mental attitude by re-educative procedure as well as by collective suggestion.

#### *The Pituitary Gland in Epilepsy.*

In the same section Dr. BEVERLEY R. TUCKER, of Richmond, Va., in a paper on the Role of the Pituitary Gland in Epilepsy, said that he believed that convulsions, whether pathological and called epilepsy or otherwise, were symptoms of underlying diseased conditions, and therefore were organic and not functional. Among these underlying conditions was a secretion of the pituitary gland. He agreed with Cushing that the pituitary secretion gave a substance which had to do with cortical cell stability, and that when the secretion was diminished or absent convulsions might ensue. Hypopituitarism was divided into two types: first, the congenital or chronic type, in which the patient gave evidence in the past of the usual syndrome of the hypopituitarism, and might have convulsions as he approached adolescence. The second or transitional type might present clinical evidence of normal or even hyperpituitary secretion in the past, but as adolescence approached diminished secretion was shown by lack of perspiration, increase in fat, increased sugar tolerance, slowed pulse, lowered blood pressure, and at times convulsions. The radiographic findings in the cases reported confirmed the clinical observations. The first type showed a small fossa with enlarged processes and roughened sella, and the second type enlarged fossa with large processes and roughened sella. These bony outgrowths encroached on the fossæ. A number of cases were reported and the satisfactory result of pituitary feeding was shown.

#### *The Therapeutic Aspect of Blood Transfusion.*

In the Section of Pharmacology and Therapeutics Dr. LESTER UNGER, of New York, spoke on the Therapeutic Aspect of Blood Transfusion, and referred to the respective merits and indications of transfusion with unmodified blood and with citrated blood. The technique of the method devised by the author was explained, as well as the microscopic method of testing the compatibility of the donor's and recipient's blood.

*Alcoholic Liquors in Relation to Health.*

Dr. LAMBERT OTT, of Philadelphia, discussed the question of light wines and beer in relation to health, and said that after 40 years of observance among wine, beer, and whisky drinkers he had come to the conclusion that the use of light wines and beer was healthful, and he thought that their sale under Federal and State supervision should be continued. He was of the opinion, however, that the sale should be closely supervised to see that no ingredients were used as preservatives which would be harmful.

## CONTROL OF VENEREAL DISEASE.

*Provision of Treatment Centres.*

SPEAKING to the Local Government Board vote in the House of Commons on June 30th, Dr. Addison suggested that the work of the 146 existing centres was good but susceptible of improvement, while at least 1000 such centres would be needed. Organisation of these centres and training of the expert personnel were a matter of time, and increase in efficiency could not be other than gradual. Compulsory notification before efficient treatment had been organised substantially throughout the country would, he thought, drive patients into the hands of inept and quacks. The numbers in attendance at the treatment centres approached half a million in 1918, having been barely over 200,000 in the previous year.

*Compulsory Notification.*

The subject of compulsory notification of venereal diseases continues to receive attention. Committees have sat on it, commissions have considered it, correspondents to the daily press have commented upon it, lecturers have enunciated their views upon it. It is time to arrive at a decision as to the desirability of initiating some scheme of notification, so that if the verdict be affirmative that scheme may be put into practice at once, or, if negative, our energies may be concentrated on other methods for the protection of society. In general we believe opinion to be in favour of a system of notification, if thereby a larger number of patients were brought under early treatment. The paramount objection advanced is the fear of deterring patients from seeking qualified treatment if they knew that this involved notification. If an unsuitable plan was put into operation there would, it is true, be reason to fear such a result. Experience in America and Australia, however, points to an efficient method to which no objection can be taken. The February issue of *National Health* enunciates the main features of the American scheme:—

The physician in the city of Chicago, as an instance, notifies the Public Health Department of Case "A," whom he is treating for syphilis. The Department registers the case with an identification number—e.g., Case 5000—and sends to the doctor literature, each leaflet of which is stamped with the patient's registered number, to hand on to him. The patient is urged to pay great attention to the instructions, which are of an educational, not a remedial, nature. If he desires for any reason to change his physician, all that will be necessary for him to do is to report his registered number to the next physician who takes up the case. He is informed that provided he continues treatment till pronounced cured, and observes the necessary precautions to prevent spreading infection, the State is satisfied, but if he fails to observe these requirements his identity will be disclosed by the physician to the Public Health Department, which will then take proceedings.

The gist of this scheme was laid before the Commission on Birth Control by Miss Norah March on June 13th, and was in harmony with the trenchant letter to the *Times* of April 5th over the signatures of Sir William Osler, Dr. Eric Pritchard, Sir William Hale White, Sir G. L. Cheate, Mr. W. H. Clayton-Greene, and Sir James Purves Stewart. As a result of the activities of the Local Government Board in opening treatment centres, of the admirable propaganda work of the National Council and its branches, and last, but not least, the information, interest, and fears which are filtering through the various social strata, the demand is undoubtedly increasing for some form of "Government action" directed towards the repression of venereal disease. Altruism and Parliamentary expediency for once are in unison and call for an immediate constructive policy. The method of notification adopted at first may not be perfect, but if elastically contrived now it can later be modified by

experience. To reduce what opposition may still linger two courses are open. Firstly, to inform large corporate bodies, representative of the industrial classes, of the innate meaning and powers for good of the scheme to be adopted. Their sympathetic interest, thus gained, should influence or compel acceptance of the scheme by their nominees. Secondly, to lay before the medical profession a concise and systematic statement of the proposed scheme in all its bearings. This would reach many who are prevented by time or distance from attending meetings or conferences. Where possible addresses should be given enabling the practitioner to answer objections encountered in the course of his professional work.

*Prophylaxis v. Early Treatment.*

Controversy still centres round the epoch at which disinfection of venereal contact is admissible. Certain obvious facts are apt to be overlooked. Whilst those who oppose earnestly the issue of prophylactic packets for fear that such facilities may tempt the fearful to plunge into venery, they are apparently forgetful of one pertinent fact. All their arguments against the use of packets are effectively advertising the existence of the very articles they refuse to sanction and are playing into the hands of the dealer in so-called rubber goods and the unscrupulous druggists, who, without actually infringing the Venereal Disease Act, are bringing these articles more and more prominently to the notice of the public. These facts must be understood and then faced.

Nothing but good can come of the frank public discussion at the Guildhall Conference of the Royal Institute of Public Health on June 25th, of which we published a long summary last week. Sir Malcolm Morris, preferring not to enter into the ethical side of the question, described prophylaxis as a panicky measure. Dr. J. H. Sequeira admitted that his opinion in regard to prophylaxis had changed after seeing important results follow from it at the treatment centre of which he was in charge. He was himself unable to differentiate ethically between supplying a man with a prophylactic outfit and giving him an address to which he could go for so-called early disinfection. Sir Thomas Barlow, whilst deprecating the issue of packets, called attention to the value of a 2 per cent. solution of ordinary yellow soap in destroying the gonococcus. It may usefully be recalled that the prophylaxis at birth of gonorrhoeal ophthalmia has been practised with conspicuous benefit for many years.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

*A League against Cancer.*

A VAST international league has just been initiated in Paris, largely owing to the efforts of Professor Hartmann, to deal with all aspects of the cancer problem—research, study of preventive means, and treatment. It bears the name of Franco-Anglo-American League against Cancer. Patrons are: Lord Bertie of Thame, the British Ambassador in Paris; Mr. William Sharp, late U.S.A. Ambassador; M. Mesureur, director of the Assistance Publique in Paris; Dr. Roux, director of the Pasteur Institute; Professor Roger, doyen of the Faculty of Medicine; and M. Leclainche, inspector-general of veterinary services. The administrative council is made up as follows:—

*President:* M. Justin Godart, late Under-Secretary of State for the Service de Santé.

*Vice Presidents:* Professor Hartmann, professor of clinical surgery in the Faculty of Medicine; Sir John Piltier, honorary president, British Chamber of Commerce; Professor Mark Baldwin, corresponding member of the Institute of France; Baron Edouard de Rothschild. *Other Members:* Mr. Laurence Benet, Mr. Walter Berry (President of the U.S.A. Chamber of Commerce), Professor Borrel, Dr. Branch, Dr. Cunéo, Professor Depage, Dr. Dabrujeaud, Dr. Helme, Major Lambert, Augustin Lumière, Professor Regaud, Professor Roger, Dr. Henri de Rothschild, Dr. Shoninger, M. Félix Vernes, M. François de Wendel (deputy). *Treasurer:* M. Deharme. *Legal Advisers:* M. Boccon-Gibod, solicitor; M. Chavanne, notary. *Scientific Committee:* Professor Roger, Professor Achard, Professor J. L. Faure, Professor Gilbert, Professor Hartmann, Professor Letulle, Professor Ménétrier (Member of the Academy of Medicine), Professor Borrel (head of the cancer laboratory of the Pasteur Institute), Professor Regaud (head of the biological laboratory of the Radium Institute), Professor Bérard and Professor Pavot (Lyon), Dr. Calmette (Lille), Professor Chavannaz (Bordeaux), Professor Forgue (Montpellier), Professor Depage and Professor Dautin (Brussels), Committee of patronesses with the Dowager Duchesse d'Uzès in France and Lady Derby in England at its head. *General Secretary:* M. Robert Le Bret, 2, Avenue Marceau, Paris. *Assistant Secretary:* Mme. (Dr.) Fabre.

A circular has been addressed to all the medical men in France calling attention to the fact that cancer claims more than 33,000 victims a year in France, and last year claimed 3420 in Paris alone. The circular insists on the benefits of early surgical interference, which gives, at the end of five years, an immunity from relapse amounting to 50 per cent. where the breast is concerned, 59 per cent. for the cervix uteri, 35 per cent. for the stomach, and 45 per cent. for the rectum. The attention of medical practitioners is called to the importance of noting the slight early signs of cancer, and these are described minutely under the various topographical headings. A questionnaire is sent out, replies to which are to form the basis of a vast inquiry, leading to a system of rational prophylaxis.

1. Is cancer frequent or not in the region where you practise? In your experience what is the cause of this frequency or relative immunity—heredity, habitat, manner of life, &c.? From the point of view of age has the date of onset of cancer been lowered?

2. Is cancer on the increase amongst your patients; if so, since when? Has this rate of increase been greater during the war? Have you observed cases of cancer occurring at the same time in husband and wife? Have you noted the existence of cancer in people dwelling together or successively in a certain house?

#### *Medical War Benefit.*

The medical benefit fund is a section of the General Association of the Doctors of France concerned with collecting subscriptions to found a relief fund for doctors and their families in difficult circumstances owing to the war. More than a million francs has already been collected in voluntary donations from the medical profession in France and abroad. At the last general meeting, at which the Under Secretary of State for the Service de Santé presided, held in the large amphitheatre of the Faculty of Medicine, it was stated that frs. 900,000 had been distributed in aid of the practitioners in the devastated districts, of widows and orphans of medical men, and of students deprived of the necessary resources for pursuing their studies.

#### *Stereoscopic Radioscopy.*

Dr. Chabry has devised a simple and ingenious method of examining radiograms in the stereoscope to produce a striking effect of relief. Two plates having been taken at a different angle they are reduced to stereoscope dimensions and placed side by side on the same slide. The first plate is then reproduced again on the far side of the second, giving three pictures side by side on the same slide. The slide thus prepared is placed in the stereoscope, when plates 1 and 2 give a fine relief of the anterior surface, and plates 2 and 3 the same relief of the posterior surface. By this manoeuvre it is claimed that a perfect localisation is obtained, and as the dimensions of the slides are small a valuable documentary collection can be made in a small space.

July 5th.

### URBAN VITAL STATISTICS.

(Week ended July 5th, 1919.)

*English and Welsh Towns.*—In the 96 English and Welsh towns with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had been 9.9, 10.0, and 9.6 per 1000 in the three preceding weeks, rose to 10.0 per 1000. In London, with a population slightly exceeding 4,000,000 persons the annual rate was also 10.0, against 9.0 per 1000 in the previous week, while among the remaining towns the rates ranged from 2.9 in Carlisle, 3.8 in Gloucester, and 4.4 in Newport (Mon.) to 15.7 in Oxford, 16.1 in Hastings, and 16.9 in Wigan. The principal epidemic diseases caused 153 deaths, which corresponded to an annual rate of 0.5 per 1000, and included 49 from infantile diarrhoea, 40 from diphtheria, 29 from measles, 15 each from scarlet fever and whooping-cough, and 5 from enteric fever. Measles caused a death-rate of 1.4 in Newcastle-on-Tyne and 1.5 in Warrington. There were 2 cases of small-pox, 1236 of scarlet fever, and 990 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 2, 1143, and 1030 respectively at the end of the previous week. The causes of 18 deaths in the 96 towns were uncertified, of which 5 were registered in Birmingham, 3 in Liverpool, and 2 in Warrington.

*Scotch Towns.*—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality, which had been 12.4, 11.0, and 11.5 per 1000 in the three preceding weeks, fell to 9.9 per 1000. The 213 deaths in Glasgow corresponded to an annual rate of 9.9 per 1000, and included 5 from whooping-cough, 4 from measles, 3 from infantile diarrhoea, and 1 from diphtheria. The 69 deaths in Edinburgh were equal to a rate of 10.7 per 1000, and included 6 from measles, 2 from whooping-cough, and 1 from infantile diarrhoea.

*Irish Towns.*—The 99 deaths in Dublin corresponded to an annual rate of 12.7, or 1.1 per 1000 below that recorded in the previous week, and included 2 from infantile diarrhoea and 1 from diphtheria. The 87 deaths in Belfast were equal to a rate of 11.3 per 1000, and included 2 from scarlet fever and 1 from infantile diarrhoea.

## Obituary.

RICHARD DANCER PUREFOY, M.D.,  
LL.D. (HON. CAUSA) DUB.,

PAST PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND;  
PAST PRESIDENT OF THE ROYAL ACADEMY OF MEDICINE IN  
IRELAND; PAST MASTER OF THE ROTUNDA HOSPITAL.

Dr. R. D. Purefoy died at his residence in Dublin on June 27th, in his seventy-second year, after a brief illness. His friends had noticed for some time that his health was failing, but it was not until a month or two ago that he admitted any loss of vigour. Early in June he went to Newcastle, co. Down, for a holiday, but he felt so ill that he came home in a few days. He was carried to his bed and gradually sank to rest.

Richard Purefoy came of a medical family, his father practising as a doctor at Lucan, a few miles from Dublin. His mother was a native of Tipperary, and it was in that county that he was born. Educated at Raphoe School, co. Donegal, and Trinity College, Dublin, Purefoy took his medical degrees in 1872. In 1879 he became a Fellow of the Royal College of Surgeons in Ireland. From the first he devoted himself to the obstetric art, and was successively assistant master at the Coombe and at the Rotunda hospitals. In the latter he worked under Lombe Atthill and George Johnston. He was for many years gynaecologist to the Adelaide Hospital, and in 1896 he returned to the Rotunda as Master. When his term of mastership was ended he was elected consulting gynaecologist to the hospital. He signalled the termination of his office by presenting to the hospital a fully equipped clinical laboratory. For many years he was very busy in practice, and for a generation he was one of the leading obstetricians and gynaecologists in Ireland. In 1912, after many years' service as a member of Council, he was unanimously elected President of the Royal College of Surgeons, being the first of his specialty to occupy the chair since 1880, when McClintock was President. It was during his tenure of office as President that Purefoy received the honorary degree of LL.D. from the University of Dublin at the Bicentenary celebrations in 1912. In 1915 he was elected President of the Royal Academy of Medicine.

By Purefoy none of the many posts of honour he held were regarded as sinecures. He fulfilled their duties in most exact manner. The Rotunda Hospital was, however, his chief interest in life. No governor in the history of that great charity ever held it in closer affection or devoted more time and energy to its welfare. Outside his professional work Dr. Purefoy was interested in music and art. Possessed of a baritone voice of good quality, in his younger days he sang in the choir of Trinity College Chapel, and all his life he was a member of many of the musical clubs in Dublin. At the time of his death he was President of a very ancient musical society—the Hibernian Catch Club, and he also collected pictures, glass, and furniture. In private a generous but keen student of life, few men of his age kept up so much interest in the advance of knowledge. Masterful in his individuality, he did not bear opposition easily, and while no one could be a better friend he was frank in his dislikes. His disappearance leaves a gap in the professional and social life of Dublin, where he was for so long a characteristic and prominent figure.

ALEXANDER SCOTT, M.D. GLASG.,

CERTIFYING FACTORY SURGEON, SOUTH-EAST GLASGOW AND TOLLICROSS.

THE death of Dr. A. Scott brings a strong sense of personal loss to medical men in the West of Scotland as well as to many employers and workers of industrial Glasgow. His original choice was the Ministry and his first work was teaching, but the very practical nature of his sympathy with workers attracted him to the practice of medicine. In 1875 he qualified M.B., C.M. in the University of Glasgow and took the M.D. degree 12 years later. Early in his medical career he focussed his attention on industrial disease, and his numerous contributions to the literature of this subject bear evidence alike to his medical acuteness and to his deep interest in the workers' welfare.

The recognition of this work by his colleagues and by the Home Office was to him not only a source of honest pride and satisfaction but also an inspiration and encouragement to

persevere. Many medical teachers and practitioners can recall valuable advice and help freely and generously given. As certifying factory surgeon he had many opportunities of investigating industrial conditions, and of these he made full use not only as a clinician but also as a sociologist, for his mind was too broad and his sympathy too deep to be fettered by the limits of his official duties. Employers and workers alike remember countless acts of unostentatious help for those handicapped in life by physical defect. A typical instance may be mentioned as an illustration. A medical friend showed Dr. Scott one of the early cases of cerebro-spinal fever in 1905—a boy who recovered but with total deafness. Six years later, when the boy was ready to leave the Deaf-Mute School, the parents were surprised to find that Dr. Scott had secured for him a situation in a drawing office, where he could learn a profession in which his deafness was no bar to progress. In spite of all his numerous and varied duties, he had never forgotten the wasted figure of the meningitic boy; and without any hint or application from outside, he had taken charge of the lad's future in his own quiet unobtrusive way.

To those who knew him this active practical sympathy explained much in his nature besides accounting for his reputation as a conscientious and safe medical referee, because it made him almost unduly sensitive to adverse or unsympathetic treatment. Actions that outsiders might attribute to personal pique were often only the natural expression of his resentment against a harshness of treatment entirely foreign to his own nature. A native of Ayrshire, he was at his best in Scottish song and story; and thousands have enjoyed the revelation of his strong personality in his popular lectures on these subjects. A sterling upright man in every relation of life, the city of Glasgow and the ranks of industrial medicine are consciously the poorer for his loss.

#### THE LATE DR. E. G. FEARNSIDES.

SUPPLEMENTING the biographical notices of Dr. E. G. Fearnside, which appeared in our last week's issue, Dr. Henry Head writes:—

"The death of Dr. Fearnside has left a gap in the ranks of the younger neurologists that cannot be filled. He possessed an unusually wide and accurate knowledge of the physiological aspects of medicine, especially neurology. His pride was to be familiar with every paper written by Gaskell and those who drew their inspiration from him; this made the review of the 'Innervation of the Bladder and Urethra' published by him in *Brain* (1917) so masterly an exposition of the work of the English school. He was the most devoted fellow-worker, and formed the coordinating member of the team working on syphilis of the nervous system at the London Hospital. No trouble was too great to perfect the records, for he had a genius for order and method, and every patient we examined was known to him personally and looked to him for help.

He showed the same self-sacrificing ardour in the service of the hospitals to which he was attached, and was always ready to take on his shoulders emergency duties without hope of reward. Out-patients have been known to weep when they heard that Dr. Fearnside was no longer in charge. He was beloved by his patients, for in each case he constantly exalted the importance of the individual rather than the disease. This was the secret of his success at the Home of Recovery, Golders Green, subsequently transferred to the Royal Air Force as a hospital for officers suffering from functional nervous disorders. He will always be remembered by those who worked with him as a physician of wide interests and unbounded kindness of heart."

PRESENTATION TO DR. MICHAEL GRABHAM.—Dr. Michael Grabham, F.R.C.P., of Madeira, has been the recipient of an illuminated address enclosed in a silver casket, from the British community, in acknowledgment of long and unwearying medical and general public service. Dr. Grabham, a most hospitable virtuoso, received on the occasion more than a hundred guests, to whom he displayed the interesting collection of scientific instruments, china, and silver, which have accumulated in his ancient Quinta; and in responding to the presentation gave a review of medical progress since his early days, and a recital on his magnificent organ, recalling to some of those present his past refined manipulation of the giant instrument in St. Paul's Cathedral. Dr. Grabham was an intimate friend of Thomas Wakley, the eldest, the Founder of this journal, whom he accompanied to Madeira on a search for health.

## Correspondence.

"Audi alteram partem."

### PORTRAIT OF SIR CLIFFORD ALLBUTT.

To the Editor of THE LANCET.

SIR,—The large number of subscribers to the Fund for presenting Sir Clifford Allbutt with his portrait has proved that the profession welcomes the opportunity of testifying to the esteem and affection with which he is regarded. Subscriptions have been received from nearly a thousand members of the profession. It had been intended to close the Fund at the end of June, but I have been asked to keep it open until July 31st. I would ask all those who wish to take part in the presentation, but have not yet notified their intention, to send their subscriptions, which must not exceed one guinea, without delay. Cheques and postal orders should be made payable to the "Sir Clifford Allbutt Presentation Fund," crossed London County, Westminster, and Parr's Bank, and addressed to the treasurer of the British Medical Association, 429, Strand, London, W.C. 2.

I may add that it is intended after the portrait in oils has been painted to commission a mezzotint engraving from it which subscribers to the Fund will be able to purchase for their own collections.—I am, Sir, yours faithfully,

G. E. HASLIP,

Treasurer.

July 7th, 1919.

### DETOXICATED VACCINES.

To the Editor of THE LANCET.

SIR,—Dr. D. Thomson's article on this subject in your issue of June 28th raises many interesting points for bacteriologist and clinician alike. The fact that the toxic portion of a bacterium can be removed by treatment with alkalies, alcohol, &c., was noted by Vaughan and his co-workers in America some years ago in their work on the cleavage products of bacterial protoplasm. These researches, which extend over a period of nearly 20 years, were brought together in book form under the title of "Protein Split Products" shortly before the war. The book contains an immense amount of practical biochemical detail which I need not enter into, but it also contains the basis of the work on which the detoxicated vaccine must rest. The authors regard the bacterium as composed of relatively complex proteins which closely resemble those of the cells of the higher animals. They found that the cellular substances of bacteria yield cleavage products identical with those obtained by the hydrolysis of vegetable and animal proteins. In animals the toxin produced from the typhoid bacillus, from egg albumin, and from the hemp-seed kill laboratory animals in much the same way, and, as Vaughan points out, there is "striking evidence of the similarity in the structure of the protein molecule, whether it be of bacterial, animal, or vegetable origin." Vaughan devised large copper tanks which were capable of containing as much as 20 litres of agar and by this means was able to produce enormous quantities of growth for his analyses. Elaborate precautions were taken to remove all traces of medium from the growth, and when this had been done some 60–80 g. of purified cellular substance remained from the growth in each tank. By acting upon the bacteria with a 2 per cent. alcoholic solution of caustic soda Vaughan was able to produce two distinct portions, a toxophor and a haptophor portion. Careful chemical analyses were made, and it was concluded from these that the toxophor element obtained from the different sources appeared to be the same, whereas the haptophor residue in each case differed from that obtained from other proteins. This haptophor residue when injected into guinea-pigs conferred immunity against the living organism (e.g., in the case of *B. coli*). Furthermore, this immunity was specific and could not be produced by other proteins such as egg albumin, whereas in the case of the toxophor group the was apparently no specificity. Vaughan believes that the splitting of bacterial protein into two portions is carried on in the human body by a proteolytic ferment produced by certain cells, and that this ferment is specific for the protein which calls it into existence. A large number of organisms were investigated in this way—*B. typhosus*, *B. anthracis*, *B. tuberculosis*, pneumococcus, and a number of saprophytic bacteria.

The results of this work are obviously of far-reaching importance. Not only are they, as has already been remarked, the basis of vaccine therapy, they are also intimately bound up with anaphylaxis, tubercular hypersensitiveness, pyrexia, and immunity problems generally. In tuberculosis especially there is a large field for research on these lines, and the authors appear to have utilised their opportunities to their full extent. They do not, however, record much in the way of clinical observation, and it is on these lines that the next step has to be taken. It seems possible that bacteria possess an external lipoidal substance soluble in fat solvents and that after this has been removed we have a protein base which can be divided, as Vaughan has shown, into two portions. At least three portions, therefore, may enter into the composition of the ordinary vaccine emulsion. It is far from unlikely there are others also, and the whole question affords a striking example—if such were needed—of how crude our methods have been in the past. The use of these newer methods in vaccine therapy on the one hand, and in the preparation of antigens for deviation of complement reactions on the other, warrants very careful clinical observation from independent observers. With such observations used as controls I believe that far-reaching results may be forthcoming.

I am, Sir, yours faithfully,  
July 7th, 1919. S. ROODHOUSE GLOYNE.

## EPIDEMIC PERINEPHRIC SUPPURATION.

To the Editor of THE LANCET.

SIR,—In connexion with the interesting correspondence upon this subject which has occupied a place in your recent numbers, it may be worth noting that during war service in the Mediterranean I saw an unusually large number of these cases as well as of perinephric inflammation which subsided without operation after rest in bed. These cases were very common in Malta in 1916 and the first half of 1917. There was, so far as I know, no influenza among the troops there, but boils and other cutaneous sores were extremely common. After the middle of 1917 I saw an unusually large number of such cases in France, but they were not, I think, in so great a proportion to the total sick as they were in Malta. The prognosis in both places was very good.

I am, Sir, yours faithfully,  
WILLIAM THORBURN,  
Late Consulting Surgeon, British Armies.

Manchester, July 6th, 1919.

## THE MAINTENANCE OF COTTAGE HOSPITALS.

To the Editor of THE LANCET.

SIR,—There has been considerable correspondence in the medical and lay press as to the need for increased hospital accommodation, especially of the cottage hospital type. The difficulty in establishing these institutions is not so much the cost of building and equipping as the fear that exists that they will be a continued and increasing drain upon the charitable public. For this reason it is important to consider the question of maintenance; there is apparently a general agreement that this should be as little as possible dependent on charity.

Take the case of an auxiliary hospital with 20 beds serving a population of 10,000. One ward of five beds would be set aside for maternity cases. The upkeep of these beds might, under the Maternity and Child Welfare Act of last year, be provided, for the greater part, by the local authority; in so far as it might not be, the cost would be met by the patients occupying them, so that this ward at any rate would in no way be dependent on charity. Another section of the hospital would consist of separate private beds for patients willing to pay such fees as would not only cover the actual cost of their maintenance, but would allow a certain profit for the institution. The number of these beds would vary with the character of the population, perhaps 5 out of 20. This would be no charge on charity. There would remain ten ordinary hospital beds. Some of the patients occupying these beds might be able and willing to pay the necessary fees, but the majority would probably not be willing, or, if willing, would not themselves be able to pay. As yet we cannot look for these payments from the National Insurance Commission, Approved Societies, or local authorities, although the latter,

under Section 131, Public Health Act, 1875, have the power to make them; but we may quite fairly point out to the public that the time cannot be very far distant when one or other of those authorities will be called upon to support these hospitals.

### Public Hospital Funds.

The most business-like system is to pay for each patient admitted the actual amount of their cost to the institution. To do this it would be much better if the public, different bodies of workers, and other groups of persons, instead of paying hospitals indefinite sums, for which they expect an indefinite amount of treatment, would each form their own hospital fund, out of which they would pay for any patient that they sent to hospital the whole of the sum required. This would be a more business-like arrangement, more fair and satisfactory for all concerned. Those using the hospital would feel a greater sense of independence. There would be no differentiation between the patients, each of whom would bear, directly or indirectly, his fair share of the expenses of the hospital. Contributors would feel a more direct interest in the management of the institution and would probably appreciate more fully the benefits that they received.

If each society or group of persons had, as suggested, its own hospital fund it would be able to pay for its own patients as occasion arose. It would not be bound to support any particular hospital. Payment would be made, not only for the in-patients, but for such out-patients as there might be. If these hospitals are used, as it is suggested they should be, for various public services, school clinics, maternity and child welfare centres, and so on, they would derive from these a certain income.

### Payment of the Medical Staff.

As to the payment of members of the medical staff, all insured persons and others for whose treatment they contract would be treated by them in hospital without any further fee. It must here be noted that there is a very real probability of the dependents of insured persons before long being granted medical and sickness benefit. For patients in the maternity ward, unless other arrangements are made, medical men, when called in by the midwife in charge, would receive the same fees as if the patients were in their own homes. For the patients of the public services the doctor would receive an agreed payment, but for all others they would make their own arrangements with each patient.

I am, Sir, yours faithfully,  
Bradford-on-Avon, July 4th, 1919. CHAS. E. S. FLEMING.

## FEES FOR SERVICE ON PENSION BOARDS.

To the Editor of THE LANCET.

SIR,—At a general meeting of the medical practitioners in the Cheltenham area, held at the General Hospital yesterday evening, at which 27 were present, 11 of whom were demobilised doctors, the following resolution was passed *nem. con.* :—

That they were willing to act on the pension boards at a rate of either (1) one guinea per session dealing with not more than five cases per session; or (2) two guineas per session lasting two and a half hours.

It was further resolved that this resolution should be sent to THE LANCET.

I am, Sir, yours faithfully,  
H. M. MEYRICK-JONES,  
July 8th, 1919. Honorary Secretary to the Committee of Medical Practitioners in the Cheltenham Area.

## HUTCHINSON'S TEETH.

To the Editor of THE LANCET.

SIR,—A recent experience has suggested to the writer that in the course of time the characteristic notch described by the late Sir Jonathan Hutchinson in the upper central incisors may disappear. Some six years ago a girl was under my treatment for multiple ulcerative adenitis of the submaxillary region and neck. She had a somewhat depressed bridge to the nose, and upper incisors which showed a slightly curving notch in the cutting edge. A diagram was made of these teeth in the case-book and a note added that they were probably Hutchinson's teeth. A Wassermann test of the blood yielded a positive result and the case was regarded as possibly one of mixed syphilitic and

tubercular infection. The girl was treated with X rays, scraping of ulcerated glands, general tonics, and several intravenous injections of neosalvarsan. Later, a course of tuberculin emulsion was administered. Considerable improvement followed and the patient discontinued attendance.

The war intervened, but soon after the Armistice, on resuming hospital attendance, the patient presented herself with active recurrence of the adenitis. On inspection the upper incisors no longer showed any characteristic notches. Presumably the free edges of the teeth had been ground flat in the interval. Certainly no one now looking at them would suspect any present or former connexion with Hutchinson's teeth. I do not know if this possible source of fallacy has been noted elsewhere, but think it of sufficient interest to warrant a brief note.—I am, Sir, yours faithfully,

Harley-street, W., July 7th, 1919. DAVID WALSH, M.D.

## THE MEDICAL DIRECTORY.

To the Editor of THE LANCET.

SIR,—The annual circular has been posted to each member of the medical profession. If it has not been received a duplicate will be forwarded on request. We shall be grateful if the recipients will return the form by an early post.

We are, Sir, yours faithfully,

J. & A. CHURCHILL.

7, Great Marlborough-street, London, W. 1, July 7th, 1919.

## Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A meeting of Fellows was held on July 3rd for the election of two Fellows to the Council, Sir George Makins, the President, being in the chair. Three vacancies should occur annually, and the term of office of Sir George Makins would have come to an end this year, but as he was President at the time of the election he became entitled to retain the position of member of the Council for another year. The result of the election was as follows:—

Votes. Plumpers.		Votes. Plumpers.	
Sir B. G. A.	404	W. F. V. Bonney	130
Moynihan	274	A. H. Tubby	114
C. S. Wallace	274	J. F. Jennings	113
F. J. Steward	163		

The President declared Sir Berkeley Moynihan to be re-elected and Mr. Wallace to be elected members of the Council. There were 667 postal votes, and 6 Fellows voted in person. Five voting papers were wasted, owing to Fellows voting for more than two candidates. Mr. H. J. Price and Mr. Willmott Evans acted as scrutineers.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—As the result of the Second Professional Examination in Anatomy and Physiology, held on June 26th, 27th, and 30th, and July 1st, for which 99 candidates presented themselves, 68 were approved and 31 were rejected. The following are the names and medical schools of the successful candidates:—

S. Ackroyd, Leeds Univ.; M. T. Ahmed, Guy's Hosp.; J. V. D. Allin and G. W. Ballance, Birmingham Univ.; V. H. Barker, London Hosp.; H. C. Blackmore, Univ. Coll.; Dora Mahalah Catman, London Sch. of Med. for Women; N. L. Capeuer, St. Bart's Hosp.; Kathleen Frances Cawthorne, Univ. Coll.; S. B. Chambers, King's Coll.; Elizabeth Maude Chilton, London Sch. of Med. for Women; T. J. Clayton, King's Coll.; H. V. Croucher, Guy's Hosp.; W. Dabbs, Birmingham Univ.; Nancy Barbara Dautell, Univ. Coll.; Enid Marcella Dixon, London Sch. of Med. for Women; Alice Elizabeth Dove, Univ. Coll.; Beatrice Emily Ebdon, King's Coll.; H. O. Eksteen, Cape Town Univ. and Guy's Hosp.; W. E. Farnham, Birmingham Univ.; W. C. Faulk, St. Mary's Hosp.; Dora Janet Fox, London Hosp.; Lena Bella Gayer, London Sch. of Med. for Women; Nancy Kathleen Gibbs, Univ. Coll., Cardiff; Louisa Patricia Gordon, King's Coll.; F. Guiver, London Hosp.; A. W. Hall, Guy's Hosp.; B. J. Hallows, St. Bart's Hosp.; E. Hardy, Guy's Hosp.; T. H. J. Hargreaves, King's Coll.; H. W. Harvey, Guy's Hosp.; Florence Reed Hodges, London Sch. of Med. for Women; R. J. Hodgkinson, Guy's Hosp.; G. H. Hogben, King's Coll.; J. Holroyd and D. Hoole, Manchester Univ.; W. D. Jenkins, Middlesex Hosp.; H. B. Jones, Guy's Hosp.; R. G. Karn, Univ. Coll.; B. L. Laver, Guy's Hosp.; Alfred Q. Logan, St. Thomas's Hosp.; O. E. J. McOustra, Univ. Coll.; Elizabeth Maitland-Jones, Univ. Coll., Cardiff; C. A. Marais, Guy's Hosp.; Kathleen Mary Matterson, King's Coll.; J. B. G. Muir, Middlesex Hosp.; R. E. Overton, Univ. Coll.; Hilda Winifred Page, London Sch. of Med. for Women; A. Pain, Middlesex Hosp.; R. E. Richards, Melbourne Univ. and King's Coll.; Hilda Marjorie Stebbing Russell, London Sch. of Med. for Women; Z. Salama, Cairo and Birmingham Univs.; K. T. Saravammuttu, Madras Med. Coll.; L. Segal, Erlangen Univ.; C. M. Sherr, Guy's Hosp.; H. L.

Slaughter, St. Thomas's Hosp.; S. Somasundram, Ceylon Med. Coll. and Middlesex Hosp.; A. E. Strawbaun, Cape Town and Guy's Hosp.; B. H. Stribling, London Hosp.; H. A. Surial, Cairo and Birmingham Univs.; M. L. Sutcliffe, Univ. Coll.; R. O. Swaine, Middlesex Hosp.; M. Theiler, St. Thomas's Hosp.; Joyce Ellen Muriel White and Catherine Mabel Williams, London Sch. of Med. for Women; G. Wilson, King's Coll.; E. T. Wright, St. Mary's Hosp.; and B. Zeitoun, King's Coll.

UNIVERSITY OF MANCHESTER.—At examinations held recently the following candidates were successful in the subjects indicated:—

### DOCTOR OF MEDICINE.

J. W. Bride, T. H. Oliver, and C. E. Sandford.

### FINAL M.B. AND CH.B. EXAMINATION.

Kathleen Doyle, Olive M. Gimson, Archibald Harris, J. G. Nolan (distinction in Surgery), O'ga G. M. Payne, F. L. Pickett, Elaine Ratner, A. E. H. Sadek, Annie G. Thompson, Marie Warman, and Ruth A. Wilson (distinction in Medicine).

Medicine.—Elizabeth C. Davies and Doris M. R. Tompkin (distinction).

Obstetrics.—Doris M. R. Tompkin.

Forensic Medicine and Toxicology.—Samuel Adler, May Blakiston, Phyllis M. Congdon, J. W. Crawshaw (distinction), Kenneth Deakin, A. M. B. Aguirre, F. R. Ferguson (distinction), Percival Fildes, Evelyn A. Garnett, E. M. Greaves, Joshua Harris, G. E. Hayward, Sylvia K. Hickson, J. B. Higgins, F. S. Horrocks, Irma M. C. Jéhanart, F. C. Jones, Gertrude B. Leigh, H. A. Lomax, W. E. Mason (distinction), Doris B. Norman, Emily M. Peach, Harry Rosenthal, Annie Rothwell, Gerald Sheehan, Annie E. Somerford, G. L. Taylor, Henry Tomlinson, Mary I. Turner, F. A. Van Collier, Raymond Williamson, and J. B. Wright.

### THIRD M.B. AND CH.B. EXAMINATION.

Pharmacology, Therapeutics, and Hygiene.—Simon Almond, G. V. Ashcroft, Nancy B. Bleakley, T. E. Coope, Muriel Coope, Eugenia R. A. Cooper, S. W. Drinkwater, Dorothy M. L. Dyson, Winifred M. Edgehill, T. N. Fisher, E. S. Frishman, Elward Gleaves, W. H. Gratrix, Albert Haworth, Ruth Hill, C. D. Hough, Marguerite F. Johnstone, Ernest Jones, J. I. Kelly, R. R. Lane, James Leather, G. H. Lees, W. L. Martland, Alexander Maude, Eva le Messurier, P. B. Mumford, Cecil Nelson, Terence O'Brien, L. S. Potter, W. E. Powell, Margaret Pownall, J. S. Robinson, F. H. Scotson, H. L. Sheehan, Margaret Single, J. W. Smith, Constance Snowden, Harry Stafford, S. N. Taylor, Solomon Wand, Norsh M. Walker, Sidney Waterworth, Robert Williamson, and J. R. Wright.

Hygiene.—R. S. van Aalten, Margaret M. F. Corbitt, and Caroline M. Edwards-Evans.

### SECOND M.B. AND CH.B. EXAMINATION.

Vincent Chaitwick and N. S. Craig.

### DIPLOMA IN DENTISTRY.

Third Examination.—Harold Walmsley.

Final Examination.—Teresa Caudon, C. E. Cardwell, and B. L. Heelan.

### UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.

—At the Convocation held on July 1st the following degrees were conferred:—

Doctor of Medicine (Essay).—Jessie Margaret Murray.

Doctor of Medicine for Practitioners of Fifteen Years' Standing.—Thomas Blanchard Sellers and Alfred Frank Tredegar (in absentia).

Master of Surgery.—William Robert Elstob Unthank.

Bachelor of Medicine and Bachelor of Surgery.—Dorothy Olga Sutherland Blair, Sujun Raj Chatterji, Ernest Dewar Charles, William Devereux Forrest, Alexander Thomas Harrison, James Richard Hughes, Leonard Wilfrid Hearn, Ram Mansoor, Hugh Ley Puxon Peregrine (in absentia), Thomas Norman Vickers Potts, William Reynolds (in absentia), Robert Sanderson, George Roebuck Woodhead, Harold Williamson, and Angus Hedley Whyte.

Bachelor of Surgery.—William Oxley Forster Sinclair.

Diploma in Public Health.—Edgar William Todd.

Licence in Dental Surgery.—Allan Maughan.

### METROPOLITAN HOSPITAL SUNDAY FUND.—The

following are among the amounts received at the Mansion

House up to July 3rd, the total amount being then £45,000:—

The Right Hon. the Lady Strathcona and Mount Royal, £3000;

St. Mark's, North Audley-street, £502; Messrs. Watts, Watts, and Co.,

Ltd., £315; Mr. John Latta, £262 10s.; Brompton Parish Church,

£230; Brixton Independent Church, £206; Mr. Alexander Miller, £200;

Lieutenant-Colonel More Nisbett, £200; St. Alphege, London Wall,

with St. Mary, Aldermanbury, £166; St. George's, Hanover-square,

£157; Wimbledon Churches, £154; Westminster Chapel, £141; All

Saints, Eustonmore-gardens, £116; Mr. A. R. Upjohn, K.C., £105;

United National Collieries, Ltd., £105; British Oil and Cake Mills, Ltd.,

£105; Messrs. W. Gardiner and Co., Ltd., £105; Messrs. Moxey, Savon,

and Co., and River Plate Coal Co., Ltd., £105; Messrs. Wilson, Sons,

and Co., £105; St. Jude's, Midway Park, £105; Mr. J. Alec Roberts,

£100; Messrs. Erlangers, £100; Mr. W. D. Graham-Menzies, £100;

Brunswick Hall, Whitechapel, £100.

### L.C.C. AMBULANCE SERVICE.—Reporting upon

the Ambulance Service, the L.C.C. Establishment Com-

mittee mentions that it has considered, in conjunction with

the Fire Brigade Committee, a letter from the British

Medical Association (Metropolitan Branch) urging that,

instead of appointing a principal administrative assistant

as proposed, the Council should appoint an officer possessing

medical qualifications. The two committees have jointly

received a deputation from the Association, but after going

carefully into the matter both committees are unanimously

of opinion that the position should be purely administrative,

and that a principal assistant should therefore be appointed.

Any medical advice required can, of course, be given by the

Council's medical officer of health.

**WEST LONDON MEDICO-CHIRURGICAL SOCIETY.**—The annual general meeting will be held at the West London Hospital on Friday, July 18th, at 5 P.M. A large attendance is desired, as the financial position of the society's journal will come up for discussion.

**HOSPITAL SUNDAY FUND AT BRISTOL.**—£4901 have been collected for the Hospital Sunday Fund at Bristol; it is hoped that £5000 will be eventually raised. This is a "record" sum and gratifying to Mr. J. H. Reed, the honorary secretary of the Fund, who is giving up the work in which he has taken a great interest for the past 21 years.

**LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.**—The annual general meeting of the London and Counties Medical Protection Society, Ltd., was held on July 2nd at the offices of the society, 32, Craven-street, Strand, W.C., Sir John Rose Bradford presiding. Major C. M. Fegen, treasurer of the society, in proposing the adoption of the annual report and balance sheet, said that the society was never in a better financial position, the reserve fund amounting to nearly £25,000. But he gave it as his opinion that the reserve should be £100,000. The report having been adopted, Sir J. Rose Bradford was unanimously re-elected president of the society.

**ROYAL DEVON AND EXETER HOSPITAL.**—In response to the appeal for £20,000 for the funds of this hospital over £10,000 have been already received.

**HARROGATE MEDICAL SOCIETY.**—A complimentary dinner was given at the Grand Hotel, Harrogate, on July 1st, by the members of the society who had stayed at home to those who had served in His Majesty's Forces. About 60 sat down, 30 of whom were guests. The chair was taken by Dr. John Gordon Black, and Dr. D'Oyly Grange proposed the health of the guests. Surgeon-Lieutenant O'Beirne Ryan responded on behalf of the Naval Medical Service, and Lieutenant-Colonel R. J. Morris, Major Ernest Solly, Major M. B. Ray, D.S.O., and Captain Shepherd Boyd for the R.A.M.C.

**DEVON EDUCATION COMMITTEE AND MEDICAL CERTIFICATES.**—At a recent meeting of the Devon Education Committee it was stated that a country medical practitioner considered he had a grievance, as a statement had been made by the attendance subcommittee that he had given medical certificates without cause, and he said that as long as that statement was on the committee's book he would not give a certificate. The school medical officer for the county, who had examined the children referred to in the certificate, said that he agreed with the medical man that they were unfit to attend school. It evidently appears as if the medical man had a grievance.

**LONDON DERMATOLOGICAL SOCIETY.**—The annual meeting of this society was held at St. John's Hospital on June 17th, Dr. A. T. Bremner, the President, being in the chair. After the presentation of the annual report and the balance sheet the following officers were elected for the year:—President: Dr. Morgan Dockrell. Honorary secretary: Dr. William Griffith. Honorary treasurer: Dr. W. Knowles Sibley. A clinical meeting followed, after which Dr. Septimus Sunderland read a paper entitled "The Baths of Old London," the first part of which appears in this issue of THE LANCET.

**SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.**—A meeting of the Court of Directors of this society was held on July 2nd, Sir Alfred Pearce Gould, the President, being in the chair. Twelve new members were elected, this being the largest number to be elected at any meeting since the centenary of the society in 1838. The death of an annuitant was announced who had come on the funds in 1890, her late husband having paid in subscriptions £38 17s; his widow and one child had received from the society the sum of £2900, the child being still in receipt of a grant of £50 per annum. It was pointed out that this case was a striking example of the benefits of joining, for relief is only granted to the widows and orphans of deceased members. The sum of £2036 5s. was voted for the payments of the half-yearly grants to the widows and orphans on the society's books—namely, 50 widows and 7 orphans. In addition, the sum of £285 was voted as a special Peace gift, each widow and orphan to receive £5. The invested capital of the society now stands at £140,000. This cannot by the bylaws be decreased, and only the income derived from it is used for the payment of grants and expenses. Membership is open to any medical practitioner who at the time of his election resides within a 20-mile radius of Charing Cross. The annual subscription varies with the age of the member at the time of his election, and starts at £2 2s.; there are special terms for life membership. Further particulars and application forms may be obtained from the secretary at the offices of the society, 11, Chandos-street, Cavendish-square, W. 1.

## The Services.

### R.A.M.C. TEMPORARY OFFICERS.

As there appears to be some misunderstanding as to certain points in connexion with the terms of the recent offer<sup>1</sup> by the War Office of engagement in the Royal Army Medical Corps for service with the Army of Occupation, the Director-General, Army Medical Service, makes the following explanation.

(1) Officers who are at present serving in the Royal Army Medical Corps under contracts for 12 or 6 months or other definite stated periods will be required to complete these engagements, with the option of entering into the new contract on termination.

(2) Officers who are serving under contracts "until the termination of the present emergency" will be eligible for demobilisation on the statutory date for the end of the war which will be published, and the gratuities payable under such contracts will be issuable on that date.

(3) All officers who are at present serving may offer themselves for service with the Army of Occupation (such service to commence on the day following the completion of their present contracts) under the terms of the recent offer—namely, for a period of 12 months or until their services are no longer required, whichever may happen first, at a salary of £550 per annum plus rations or the allowance in lieu. The sum mentioned is inclusive of both bonus and gratuity, and no additional emoluments of any kind are issuable.

(4) Officers holding the acting rank of Lieutenant-Colonel or Major will be required to sign a contract embodying the above terms, but will draw the pay and allowances of their acting rank whilst holding it, the contract terms as to emoluments remaining in abeyance during that period; they will revert to contract rates on ceasing to hold the acting rank.

(5) Field officers of the Territorial Force and Special Reserve will receive the pay and allowances of their substantive field or acting rank.

(6) Officers will continue to draw children's allowance for the present.

### ROYAL NAVAL MEDICAL SERVICE.

Surg.-Comdr. (acting Surg.-Capt.) P. W. Bassett-Smith specially promoted to the rank of Surgeon-Captain in recognition of services rendered.

To be temporary Surgeon-Lieutenant: D. H. Cameron.

### ARMY MEDICAL SERVICE.

Col. S. G. Allen retires on retired pay.

### ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. S. H. Fairrie retires on retired pay.

Temp. Maj. (acting Lieut.-Col.) W. Robertson (Captain, R.A.M.C., T.F.) relinquishes his temporary commission on re-posting.

Captains to be acting Majors: K. P. Mackenzie, E. A. Strachan.

To be Captains: Capt. (acting Major) H. A. Sandiford, from T.F.; Temp. Capt. C. B. Hogg, E. E. Holden, W. Moodie, A. Mearns, F. H. Woods, F. A. L'Estrange.

Temp. Capt. R. S. Miller to be acting Major.

Lieutenants (temporary Captains) to be Captains: G. D. Gripper, G. T. Baker, H. C. Watson (acting Major) (and retains his acting rank), G. T. Gimlette.

Capt. N. V. Lothian to be acting Major whilst specially employed.

Capt. C. J. O'Reilly resigns his commission.

Capt. L. G. Bourdillon is seconded for service with the Egyptian Army.

To be seconded for service under the Civil Administration of Mesopotamia: Capt. and Bt. Majors A. G. J. MacIlwaine, L. Dunbar; Capt. T. J. Hallinan, P. A. With, O. D. Jarvis.

Temp. Capt. H. F. Mullan relinquishes the acting rank of Major on re-posting.

Late Temp. Capt. to be Capt. R. Marshall, H. W. M. Kendall, S. B. Faulkner.

To be Lieutenants and to be temporary Captains: Capt. G. H. Barry and T. Stanton, from Special Reserve; Temp. Capt. H. J. Davidson and T. H. Twigg.

Officers relinquishing their commissions: Temp. Lieut.-Col. J. C. Muir, and retains the rank of Captain; Major W. C. Devereux, and retains the rank of Major. Temp. Major E. H. Cooper granted the rank of Lieutenant-Colonel. Temporary Majors retaining rank of Major: J. R. Bibby, C. V. N. Lyne (Major, retired, Indian Army), W. McDougall, A. Drury.

Temporary Hon. Majors retaining the honorary rank of Major: W. K. Carew, S. Bousfield. Temporary Captains: W. G. Cobb, B. Suggitt. Temporary Captain granted the rank of Lieutenant-Colonel: G. D. Hindley. Temporary Captain and Brevet Major retaining the rank of Brevet Major: F. H. Bahr. Temporary Captains granted the rank of Major: A. V. Poysse, W. F. Law, M. A. Power, C. M. Kennedy, H. G. Joyce, J. Clayton, K. G. Fraser, J. W. Linnell, N. G. W. Davidson, W. C. Horton, E. T. Williams, E. W. Nairn, M. P. Paton, G. T. Foster Smith, G. H. Darlington, A. W. Rowe, G. C. Chubb, R. E. F. Pearse, H. F. Warwick, L. F. Hemmans, A. C. Sturrock, G. W. Riddel, P. R. Woodhouse, J. W. Applegate.

Temporary Captains retaining the rank of Captain: A. H. Turner, J. W. A. Wilson, J. W. Tocher, F. J. Cutler, L. C. Dillon-Kelly, W. J. D.

<sup>1</sup> THE LANCET, June 28th, p. 1137.

Bromley, J. Lox, P. W. Moore, T. J. Lloyd, B. T. Lang, H. Bardsley, W. Browne, W. H. Parkinson, C. W. Forsyth, L. N. Lee, R. Parry, J. Brown, V. G. Maitland, J. Graham, F. Jubb, C. G. Lambie, J. D. Oliver, E. J. Clark, E. C. Malden, J. M. Hall, H. C. Quirke, C. D. Holdsworth, D. M. Baillie, L. D. Saunders, G. S. Brown, E. P. Scott, E. H. Udall, E. W. Smerdon, A. J. Beadel, A. N. Hodges, W. J. Henry, G. H. Steven, R. R. Armstrong, H. Farncombe, S. McMurray, F. H. Pickin, R. Nunn, K. D. Melville, J. R. Prytherch, H. F. Blood, J. C. McMillan, R. H. Calvert, E. A. Morgan, J. R. Cameron, J. Paton, A. Reynolds, A. N. Hooper, A. Rutherford, R. Duncan, T. C. Hynd, W. C. Innes, W. A. Easton, W. B. Gordon, C. E. Harrison, J. W. Fox, J. E. Finlay, D. J. Evans, S. G. Graham, J. B. Ball, W. L. Webb, M. L. Farmer, R. Cope, G. Davidson, J. G. Garson, W. R. G. Hamilton, F. W. Milne, M. J. Fraser, M. D. Mackenzie, G. E. Lloyd, R. E. Moves, J. F. Jennings, C. G. Mackay, A. F. Morcom, A. V. McMaster, A. E. Staffurth, W. J. Woodman, W. Duguid, S. C. Pritchard, W. S. Sheppard, A. H. Aldridge, J. S. Dunn, G. R. C. Wilson, T. B. Welch, S. G. Kean, F. J. Dunne, J. Watson, H. Stokes, H. W. Smith, R. M. Wishart, H. E. S. Stiven, A. R. Moore, R. Denham, C. C. Morrell, W. R. Wiseman, R. G. Abrahams, D. A. Hutcheson, W. Reid, W. O. Roberts, G. E. Stephenson, N. M. Cummins, J. C. Lorraine, H. F. Mullan, A. St. Johnston, W. K. Calwell, J. W. McLeod, C. Cameron, W. P. Morgan, L. E. Williams, D. S. Pracy, J. Wyper, O. L. V. de Wesselow, W. H. Thresher, D. Meek, F. H. Moran, C. T. W. Hirsch, J. B. Wall, W. D. Kirkwood, A. G. East, T. Winning, D. Waluwright, J. H. Johnston, J. Williamson, G. B. Richardson, J. M. Taylor, W. N. Montgomery, P. Cheal, L. Wayne-Morgan, G. Whittington, W. G. Bullock, F. H. Alexander, J. E. R. Orchard, D. P. Smith, W. E. Bullock, C. W. Somerville, A. K. S. Wyborn, A. M. Clark, S. Churchill, M. S. Baines, F. D. Cairns, M. J. Ahern, J. W. Cowie, W. V. Coffyn. Temporary Lieutenants retaining the rank of Lieutenant: A. D. Pringle, J. C. Bell, C. H. C. Casen.

#### Canadian Army Medical Corps.

Temporary Lieutenant-Colonels (acting Colonels) to be temporary Colonels: W. T. M. MacKinnon, F. Guest.

Temporary Majors (acting Lieutenant-Colonels) relinquishing the acting rank of Lieutenant-Colonel: J. L. Cock, G. W. Treleaven, A. H. Taylor.

Temporary Captains (acting Majors) relinquishing the acting rank of Major: C. K. Dowson, R. B. Mitchell.

Temporary Captains (acting Majors) to be temporary Majors: A. W. Bagnall, H. C. Mersereau, J. Seager, H. K. Bates, H. H. Argue, L. A. Richmond, J. McCulloch, F. T. Campbell, H. M. Barrett, F. H. Pratten, F. W. Lees, E. Douglas, L. C. Palmer, A. P. Chown, F. J. Tees, W. V. Lamb, D. P. Hanington, R. N. W. Shillington, W. J. MacKenzie, J. H. Moore, W. A. Wilson, S. R. Johnston, T. M. Creighton, F. F. Duhamel, A. G. MacLeod, D. A. Clark, C. E. Preston, F. W. Blakeman, V. N. MacKay, J. A. Murray, F. B. Bowman, A. B. Schinbein, M. H. Allen, W. Ross, W. G. Coshie, C. B. Anderson, C. R. Waldron, F. V. Woodbury, H. W. Wadge, T. R. Little, E. L. Pope, R. R. Barker, H. G. Wood, J. J. Thomson, H. O. Boyd, A. Blais.

Honorary Captains (acting Honorary Majors) to be Honorary Majors: A. E. Clifton, H. J. Tester, J. W. White.

Honorary Lieutenants (acting Honorary Captains) to be Honorary Captains: J. F. Christie, H. T. Cameron, A. P. Ross, W. R. Duff, H. G. Illife, F. White.

#### GENERAL RESERVE OF OFFICERS.

Major J. W. Jennings to be Lieutenant-Colonel.

#### SPECIAL RESERVE OF OFFICERS.

Capt. (acting Major) W. McN. Walker relinquishes the pay and allowances of his acting rank.

#### TERRITORIAL FORCE.

Majors (acting Lieutenant-Colonels) relinquishing their acting rank on ceasing to be specially employed: J. W. Bird, D. H. Weir, W. A. Thompson, H. T. Samuel, R. T. Turner.

Capt. (acting Lieut.-Col.) E. Knight relinquishes his acting rank on ceasing to be specially employed.

Major (acting Col.) H. Richardson relinquishes his acting rank on vacating the appointment of Assistant Director of Medical Services.

Capt. (acting Majors) relinquishing their rank on ceasing to be specially employed: T. B. Layton, R. Phillips, W. F. B. Bensted-Smith, J. H. Jordan, P. S. Martin, F. H. Robbins, W. T. Gardner, A. W. Hayward, H. B. Cunningham, J. C. S. Dunn.

Capt. (acting Major) L. P. Harris relinquishes his acting rank on vacating the appointment of Deputy Assistant Director of Medical Services, and is restored to the establishment.

Capt. (acting Major) S. F. St. J. Steadman relinquishes his acting rank on vacating the appointment of Deputy Assistant Director of Medical Services.

Capt. (acting Major) P. C. P. Ingram relinquishes his commission and is granted the rank of Major.

1st Eastern General Hospital: Capt. C. H. Budd is restored to the establishment.

Sanitary Service: Capt. W. Robertson is restored to the establishment on ceasing to hold a temporary commission in the R.A.M.C.

2nd London Sanitary Company: Lieut. C. J. Regan to be Captain.

#### TERRITORIAL FORCE RESERVE.

Capt. E. S. Taylor, from 2nd London Casualty Clearing Station to be Captain.

#### ROYAL AIR FORCE.

Medical Branch.—Capt. H. T. H. Butt, W. F. Walker, R. H. Dixon, and Lieut. G. M. Mellor are transferred to unemployed list.

Dental Branch.—Lieut. H. Wardill is transferred to unemployed list.

#### INDIAN MEDICAL SERVICE.

Majors to be Lieutenant-Colonels: G. P. T. Groube, E. D. W. Greig, W. E. McKechnie, F. F. Harvey, W. C. H. Forster, J. J. Urwin, D. McCay, A. B. Fry, E. C. G. Maddock, W. H. Dickinson, A. W. Tuke, G. H. Stewart.

At the last meeting of the Launceston (Cornwall) board of guardians Dr. W. F. Thompson resigned the post of medical officer for the No. 3 district after 35 years' service.

## Parliamentary Intelligence.

### HOUSE OF COMMONS.

WEDNESDAY, JULY 2ND.

#### Treatment of Tuberculous Pensioners.

Sir J. D. REES asked the Pensions Minister what steps he proposed to take to provide for concurrent treatment and training on the colony system of pensioners suffering from tuberculosis; and whether he had under consideration the proposals on this behalf of the East Midlands Joint (Disability) Committee. — Major ASTOR (Parliamentary Secretary to the Ministry of Health) replied: The Inter-Departmental Committee on Tuberculosis have under consideration the question of the provision of colonies for the concurrent treatment and training of discharged men suffering from tuberculosis, and I understand that the report of the Committee is expected very shortly. My right honourable friend has been informed of the proposals for the acquisition of an estate in Derbyshire for the concurrent treatment and training of discharged men suffering from tuberculosis, and I will instruct one of the medical inspectors to visit the estate and report upon the scheme.

THURSDAY, JULY 3RD.

#### Welsh Board of Health.

Brigadier-General Sir OWEN THOMAS asked the Minister of Health whether it was proposed to give representation on the Welsh Board of Health to the executive committee of the Welsh National Memorial Association, to the North and South Wales nursing associations, and to the executives of North and South Wales soldiers' and sailors' disablement committees. — Major ASTOR replied: As I stated in reply to a question by the honourable and gallant Member on June 30th, the Board is not yet complete; but I may point out that Section 5 of the Ministry of Health Act requires the persons constituting the Boards to be officers of the Ministry, and that this requirement excludes the possibility of adopting the principles suggested in the question as determining the nature of future appointments to the Board. The important bodies referred to in the question will probably be asked to suggest suitable names of persons for membership of the Consultative Council of the Ministry of Health in Wales.

Brigadier-General Sir OWEN THOMAS asked the Minister of Health if he would state what was the amount of the total remuneration paid to those Commissioners of the Welsh Insurance Commission, now transferred to the Welsh Board of Health, during the period of war; what time was devoted by them to the specific duties of the Commission during that period; what was the salary to be paid to the chairman, members, and officers of the Welsh Board of Health already constituted; and what further salaries, if any, were to be paid to the members of the Board yet to be appointed. — Major ASTOR replied: The remuneration of the three members of the Welsh Insurance Commission who have now been appointed members of the Welsh Board of Health was at the rate of £1000, £1200, and £1000 per annum respectively, and no change has been made in these rates on their transference. The whole time of the Commissioners was very fully occupied with Health Insurance work, except in so far as they undertook various forms of temporary war work from time to time. The point in the last paragraph of the question has not yet come up for decision and no decision has been taken on it.

#### National Health Insurance Bill.

Major ASTOR (Parliamentary Secretary to the Ministry of Health) moved the second reading of the National Health Insurance Bill. He said it was not in any way an attempt to amend the Insurance Act, 1911. The whole object of the Bill was to maintain as far as possible the status quo. Because of the change in money values a large number of people who in 1911 were earning round about £100 were now earning something like £250. The original Act, which made insurance compulsory for non-manual workers with a low income, would, unless this amendment were made, drive out of insurance nearly 1,000,000 insured persons. In selecting the figure of £250 instead of £160 they had been guided by the award of the Conciliation and Arbitration Board for Government employees. It would be a real hardship if, having contributed over a considerable period towards insurance, anything up to a million persons were to lose the benefit of their contributions, and that would happen as from June 30th last unless this small Bill were passed. If this Bill were not passed a large number of medical men who dealt with insured persons would lose their patients. He had received deputations from medical men. There was one point which was raised, and that was the bringing into insurance of that very limited class—some 20,000 or 30,000 people so far as

they were able to estimate—who would for the first time he brought into insurance. He told the deputation that they did not want to bring these people into insurance, but that they found it administratively impossible to exclude them. They tried to frame a clause which would exempt them, but were unable to do so. He asked his honourable friends to do the same, and if in Committee they were able to put down an amendment which carried out their intention, and what the Government would like to include in the Bill, they would be pleased to accept it.

#### *Criticism of the Bill.*

Major FARQUHARSON said that he quite agreed that there existed a necessity for some such Bill, and he was quite sure that the whole community, with the medical profession as well, would agree that people who were now insured persons, and had been for some time insured persons, should not lapse their insurance benefits because of the altered values of money. But he had to find fault with the text, and with the effect of the Bill. The text was so framed that the annual income was taken as a basis for determining that certain people should now be in insurance who had not been in insurance before. The new limit of £250 meant that a large number of entrants into insurance benefits were legalised by statute. He had not the slightest objection to everybody and anybody obtaining insurance benefits, but let them remember that the position they were now in was standardised and fixed by statute. The medical men made certain definite binding contracts that they would attend people whose incomes did not exceed £160. Those contracts were now in existence and were passed in review at the end of each year. The medical profession had a right to stand upon the sanctity of a contract, and to demand that they should not be penalised for the benefit of any section of the community. He would take this question from the point of view of the panel practitioner. The Government had contracted with him at the present time to do certain definite things under certain definite rules. This had been departed from. Take the case of the non-panel practitioner—the middle-class non-panel practitioner attending people for small fees. By this Bill all these non-manual workers, such as clerks, would be compelled to be insured. Major Astor's estimate was the merest conjecture. The number might be very large or very small, but on the one hand the Government was destroying a contract of service with the panel practitioners, and on the other destroying a great many practices of men working hard for a livelihood. At this time, when great schemes of medical service were coming before the country, he thought this was a most inopportune moment to tamper with a contract of service. He appealed to the Government to accept some modification of the Bill which would enable at least a postponement of new entrants into insurance and for the whole scheme of medical insurance to be considered.

#### *An Amendment.*

Captain ORMSBY-GORE moved:—

"That this House declines to proceed with a measure which increases the number of persons compelled to make contributions towards the funds administered by the National Health Insurance Commissioners without guaranteeing acceptable medical service to all insured persons and without establishing the principle of free choice both by patient and medical practitioner."

He said that he did think that it was fair to say that sufficient attention had not been paid to the point of view of panel doctors and also non-panel doctors. The intention of Parliament in the original Act, Clause 15, Subsection (3), had not been carried out. The National Health Insurance Commissioners and the Committees set up under that Act had not provided acceptable medical service to insured persons where those insured persons were either unwilling or unable to make use of the services of the panel doctors. The result was that in the town of Stafford a few panel doctors had far more patients than they could pay attention to, and the remainder of the doctors got nothing from the Insurance Committee or the Insurance Fund. Still, they were dealing with over 700 insured persons, and these had to pay twice over. That was a grievance which had to be redressed. If the insured persons were to be considered with respect to wages, the doctors ought to be considered too.

Captain ELLIOT seconded the amendment. The main point he wished to make was that the Insurance services just now from a medical point of view were not satisfactory. Great services under the Insurance Act were still being given for charity as they were before. The services of consultants, surgeons, and so on were being given just the same as before. He did not think that was a fitting way for service to the sick of this country to be rendered.

Lieutenant-Commander KENWORTHY hoped that the amendment would not be pressed. In most parts of the country, though possibly not in Stafford, the Insurance Act was giving satisfaction to the insured. He was interested in the indignation of Major Farquharson when he told the

Government of the hardships of the medical practitioner at the present time and threatened that the doctors would form a trade-union. They were in a trade-union.

Honourable Members: No!

Commander KENWORTHY: Yes, they are in the most exclusive union in the country.

Honourable Members: No! No!

Captain ELLIOT: But they do not strike.

Commander KENWORTHY: They have threatened to strike in the past. Continuing, the honourable Member said he was sure that Members on that side of the House would be only too glad to support any motion made by the Minister of Health to increase the fees chargeable by panel doctors, for he thought it was recognised that they had a hard case and that it should be done. But let them get this Bill through first.

Sir P. MAGNUS said that while he was prepared to support the second reading of the Bill he thought that very important and drastic changes should be made in it.

After further discussion, Major ASTOR appealed to the mover of the amendment not to press it. The point he made he thought was already met, as the persons brought in would have the right of claiming a certificate of exemption. As regarded what Captain Ormsby-Gore had said about the insured persons in his constituency, that was not a matter of legislation but of administration. He could assure him that the Minister of Health and himself would go into the matter and see if anything could be done. He welcomed this opportunity of paying a tribute to the splendid services which the medical profession had rendered to the wounded in France and England during the war. They all realised that, and also the extent to which they could count upon the profession in the future in the administration of the Ministry of Health.

Captain ORMSBY-GORE withdrew his amendment and the Bill was read a second time and referred to a Standing Committee.

FRIDAY, JULY 4TH.

#### *Nurses' Registration Bill.*

The adjourned debate on the Report Stage of the Nurses' Registration Bill was resumed.

Major NALL said that he had received a letter from the College of Nurses intimating that on the Government undertaking to introduce a registration Bill for nurses they were ready to withdraw their Bill in the House of Lords. The promoters of the Bill now before the House had refused a week ago to withdraw it, and as there was now very little time to consider the amendments on the paper he moved that the further consideration of the Bill should be adjourned in order that it might be allowed to lapse.

Captain BARNETT protested against the organised opposition to this Bill, and said that but for this there would have been ample time to get it through its various stages and send it up to the House of Lords, where some agreement might have arrived at. He hoped the Ministry of Health would nevertheless have the courage to bring forward a measure on behalf of the Government.

Major ASTOR nodded assent.

The motion to adjourn the further consideration of the Bill was agreed to.

#### *Syphilis Treatment.*

Mr. WATERSON asked the Minister of Health whether his Department was taking any action in regard to the recent death of a girl in St. George's Hospital while undergoing treatment for congenital syphilis; what drug was used in this case, and whether it had received the approval of his Department; whether he proposed to continue to approve of the use of such drugs; whether it was a fact, as stated by a medical witness at the inquest, that there had been a crop of such cases at Cambridge and Dublin during the war; how many deaths of this description had occurred in England and Wales since the beginning of the war; and whether he would make arrangements for the immediate report to his Department of all such deaths, both among soldiers and ex-soldiers and in the general population, in order that careful records might be available for reference?—Major ASTOR (Parliamentary Secretary to the Ministry of Health) replied: The answer to the first part of the question is in the affirmative. The case referred to is under inquiry by the Special Committee appointed by the Medical Research Committee to investigate the results of the treatment of syphilis by salvarsan and its substitutes. I understand that the drug used in this case was novarsenobillon, which is one of the drugs approved by my Department for the treatment of syphilis and tested under arrangements made by the Medical Research Committee. I am not aware of any sufficient reason for discontinuing the approval of the use of this and similar drugs. In this connexion I may add that I understand the coroner's finding at the inquest on this case was that this drug was properly administered and in proper amount. I understand that there have been several fatal cases following, though not necessarily caused by, the adminis-

tration of these drugs in military hospitals at Cambridge and Dublin during the war, and these cases also are under investigation by the Special Committee. No precise information is at present available as to the number of deaths of this description which have occurred in England and Wales since the beginning of the war, but the total number is, of course, very small, especially in proportion to the very large number of injections of such drugs taking place daily. The suggestion in the last part of the question will be considered with the report of the Special Committee when it is received. Already my Department have been considering the desirability of requiring special reports direct to the Ministry of all exceptional results following the administration of these drugs.

TUESDAY, JULY 8TH.

#### Medical Demobilisation.

Mr. MACQUISTEN asked the Secretary for War if he would state what was the general policy of medical demobilisation; why the promise given by the Ministry of National Service in November, 1918, that the demobilisation of medical men with long service or with practices to return to would be effected rapidly by replacing them with newly qualified graduates had not been given effect to; and how many, if any, temporary commissions in the Royal Army Medical Corps had been granted since the Armistice.—Mr. CHURCHILL replied: The demobilisation of an individual medical officer is left in the hands of the General Officer Commanding-in-Charge concerned, and the policy is to release first those who, on account of age, length of service, personal hardship, public expediency, &c., are considered most deserving of consideration. It will readily be understood that even then it is impossible to meet every claim, as it is still found necessary to retain certain officers possessed of special qualifications and for whom it is found impossible to find substitutes. Any applications received by the War Office are given every consideration, and when the claims of either an individual medical officer or the application of any public body for the services of a particular officer come under any of the above categories every effort is made to obtain his release, but his claim has to be considered in conjunction with the claims of other officers serving in the same Command at home or Expeditionary Force overseas. No temporary commissions have been granted in the Royal Army Medical Corps since the Armistice, but a new contract has now been approved whereby it is hoped that a large number of recently qualified medical men will volunteer for service overseas, and thus enable those who have served longest to be released.

#### BOOKS, ETC., RECEIVED.

- BAILLIÈRE, TINDALL, AND COX, London.  
Care of the Nose and Throat. By W. Stuart-Low, F.R.C.S. Eng. Pp. 63. 3s. 6d.

## Appointments.

- GAMGEE, LEONARD P., F.R.C.S., has been appointed Professor of Surgery in the University of Birmingham.
- GOODBODY, F. W., M.D. Dub., M.R.C.P. Lond., Lecturer in Medical Chemistry in University College, London.
- GRAY, H. T., F.R.C.S. Eng., Honorary Surgeon to the Infants Hospital, Vincent-square, Westminster.
- JUPP, EDGAR NORMAN, M.D. Brux., L.R.C.P., M.R.C.S., Medical Officer and Public Vaccinator for the North Chardstock District of the Axminster (Devon) Union.
- LISTER, A. B. J., Major, I.M.S., M.B., B.S. Lond., F.R.C.S. Eng., an Honorary Surgeon to H.E. the Viceroy and Governor General of India.
- LUMSDEN, THOMAS, Medical Referee to the Ministry of Pensions for Westminster.
- SANDILAND, E. L., M.B., B.S. Lond., D.P.H., Resident Medical Officer to the Croydon Borough Sanatorium.
- SHATTOCK, CLEMENT E., M.D., M.S., F.R.C.S., Surgeon to Out-patients, Paddington Green Children's Hospital.
- WALKER, C. D., M.B., Ch.B. Edin., one of the Medical Referees under the Workmen's Compensation Act, 1906, for the County Court Circuits Nos. 13 and 18.
- WOODRUFF, D., Medical Officer and Public Vaccinator for the No. 9 District of the Bodmin (Cornwall) Union.
- University of St. Andrews.—PRICE, L. T., M.B., Ch.B. Edin., Professor of Surgery; CHARTERIS, F. J., M.B., Ch.B. Glasg., Professor of Materia Medica.

## Vacancies.

For further information refer to the advertisement columns.

- Bath, Royal Mineral Water Hospital.—Two S's.
- Birmingham General Hospital.—Res. M.O. £155. Hon. S. Hon. Aural S. and Laryngologist. Asst. P. £50. Surgical Registrar. £200.
- Botolph Claydon Hospital, Wandsworth Common, S.W.—H.S. £150.
- Bristol, Cosham Memorial Hospital, Kingswood.—Res. M.O. £200.
- Bury County Borough.—Asst. M.O.H., Asst. Sch. M.O., and Asst. Tuberc. O. £500.
- Bury, St. Edmund's, West Suffolk General Hospital.—Res. H.S. £175.
- Canterbury, Kent and Canterbury Hospital.—Jun. Res. M.O. £150.
- Cheam, Surrey, St. Anthony's Hospital.—Res. M.O.
- Chelmsford Borough.—M.O.H. and Sch. M.O. £600.
- Chelsea Hospital for Women, Athurst ed, S.W.—H.S. £120. Also Registrar. £50.
- Chorley Borough Education Committee.—Asst. Sch. M.O. £400.
- Darlington General Hospital.—H.S. £225.
- Devonport, Royal Albert Hospital.—Res. H.S. £200.
- Didworthy, Devon and Cornwall Sanatorium.—Locum Tenens. 6 gs. a week.
- Edinburgh City.—Clin. M.O. under Venereal Diseases Scheme. £750.
- Ezeler, Royal Devon and Exeter Hospital.—Sen. H.S. £250.
- Gravesend Hospital.—H.S. £200.
- Great Northern Central Hospital, Holloway, London.—Oph. S.
- Grosvenor Hospital for Women, Vincent-square, Westminster.—Surgical Registrar.
- Hospital for Consumption and Diseases of the Chest, Brompton.—H.P. Hospital for Sick Children, Great Ormond-street, London, W.C.—P. and S. Also Surgical Registrar. £200. Also H.S. £50.
- Isleworth Infirmary.—Sec. Asst. to Med. Supt. £300.
- Khartoum, Wellcome Tropical Research Laboratories.—Assistant Bacteriologist. £E.600.
- Leeds Education Committee.—School M.O.'s. £400.
- Leeds University.—Lect. in Experi. Phys. £500. Demonstr. in Phys. £250. Demonstr. in Hist. £250.
- Liverpool, Forest Hill District.—M.O. £185.
- Liverpool, Fazakerley Sanatorium for Tuberculosis.—Asst. Res. M.O. £250.
- Liverpool School of Tropical Medicine.—Asst. Lect. in Parasitology. £250.
- L.C.C. Hackney Institute, Dalston-lane.—Lecturer of Sanitary Science. 30s. an attendance.
- London Hospital, E.—Surgical Registrar. Also First Asst.
- London Lock Hospital, 233, Harrow-road, W.; 91, Dean-street, Soho, W.—Registrar.
- London (Royal Free Hospital) School of Medicine for Women.—Two Demos. of Anat. £250. Also Female Pharm. £250.
- London Temperance Hospital, Hampstead-road, N.W.—Asst. Res. M.O. £120. Also Casualty Officer. £120.
- Midstone, West Kent General Hospital.—H.S. and Asst. H.S. £250 and £125.
- Manchester, Croxley Sanatorium.—Asst. M.O. £100.
- Manchester Ear Hospital, Grosvenor-square, All S. Ints.—H.S.
- Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Hon. Asst. P.
- Manchester Royal Eye Hospital.—Jun. H.S. £120.
- Manchester, St. Mary's Hospitals for Women and Children.—Three H.S.'s £100.
- Merthyr Tydfil County Borough.—Female M.O. for Maternity and Infant Welfare Work. £500.
- Metropolitan Borough of Deptford.—Asst. M.O. H. £400.
- Otago University, New Zealand.—Prof. of Syst. Med., Prof. of Clin. Med. and Therap., and Lect. on Clin. Med. £600, £500, and £400 respectively.
- Prince of Wales's General Hospital, Tottenham, N.—Hon. Asst. P., Hon. Med. Regist., and Hon. Anesth. Also Clin. Assts.
- Queen Charlotte's Lying-in Hospital, Marylebone-road, N.W.—Phys. to Out-patients.
- Queen Mary's Hospital for the East End, Stratford, E.—Hon. Ophth. S's. Also H.S.
- Rossall School, Fleetwood.—Res. M.O. £250.
- St. Helens County Borough.—Asst. M.O. H. £500.
- St. John's Hospital for Diseases of the Skin, 43, Leicester-square.—Electro-Therapeutist. £100.

St. Marylebone General Dispensary, 77, Welbeck-street, Cavendish-square, W.—Res. M.O. £150.  
 St. Peter's Hospital, Henrietta-street, Covent Garden, W.C.—Anaesth. £25.  
 Sheffield Royal Infirmary.—Asst. H.P. £150. Oph. H.S. £150.  
 Southampton County Borough Isolation Hospital.—Res. M.O. £400.  
 Stockport County Borough Education Committee.—Sch. Doctor. £400.  
 Tingwall, Whiteness, and Weisdale Parish.—M.O. and Pub. Vac. £45.  
 Tottenham Maternity and Child Welfare Committee, Amlenatate Clinic.—Female M.O. £1 11s. 6d. per session.  
 University College Hospital, Gower-street, W.C.—Res. M.O. £150.  
 Victoria Hospital, Tile-street, Chelsea, S.W.—H.P. and H.S. £100.  
 Wolverhampton and Staffordshire General Hospital.—Path. & Bac. £350. Also Res. M.O. £200.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Basingstoke (Hants) and Newport (Pembroke).

## Births, Marriages, and Deaths.

### BIRTHS.

DICK.—On July 3rd, at Walton Lodge, Walton-on-the-Hill, the wife of F. A. Dick, M.B., of a daughter.  
 SELLS.—On July 2nd, at Westcliff-on-Sea, the wife of Roland Sells, M.R.C.S., L.R.C.P., of a son.  
 STOWELL.—On July 6th, at "Fir Grove," Northwloh, Cheshire, the wife of Thomas E. A. Stowell, F.R.C.S. Eng., of a son.

### MARRIAGES.

JONES—DUGDALE.—On July 1st, at St. Pallip's Church, Blackburn, William Edmund Jones, M.R.C.S., L.R.C.P., of Blackburn, to Edith Muriel, youngest daughter of the late Adam Dugdale and of Mrs. Dugdale, of Griffin Lodge, Blackburn.  
 LYNCH—DOUGHTY.—On July 1st, at St. Peter-upon-Cornhill, B.C., Arthur Louis Lynch, M.D., C.M., F.R.C.S., Capt. R.A.M.C., to Janet Hunter Elizabeth (Jean) Doughty, daughter of the Rev. George Bell Doughty and Mrs. Janet Hunter Doughty, Westbourne-gardens, W.  
 McMASTER—STEWART.—On July 2nd, at All Saints, Kenley, Surrey, Archibald Coterill McMaster, M.B., F.R.C.S.E., to Netta, daughter of the late James Henry Fowler Stewart, Ardross, Ross-shire.

### DEATHS.

COLLINS.—On July 9th, at Sproxtton, New Wanstead, Frank Collins, M.R.C.S., L.R.C.P., suddenly, after many months of ill-health.  
 DODD.—On July 3rd, at Drummond-road, Bournemouth, Henry Allnutt Dodd, M.R.C.S., L.S.A., aged 90.  
 SELLS.—On July 4th, at the R.A.F. Hospital, Swanage, Captain Clement Peronet Sells, M.C., R.A.M.C. (T.), aged 23.  
 N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments, and Answers to Correspondents.

### THE BATHS OF OLD LONDON.<sup>1</sup>

By SEPTIMUS SUNDERLAND, M.D. BRUX.,

CONSULTING PHYSICIAN, ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN; OBSTETRIC PHYSICIAN TO THE FRENCH HOSPITAL.

#### PART I.

#### "The City of the Waters."

I LIKE to believe that the meaning of the word London is "The City of the Waters," after the derivation put forward by Mr. W. Owen, F.S.A., editor of "Welsh Archaeology"—namely, Llyn, meaning a lake or broad expanse of water, and Dyn, meaning a town. Another derivation is Lhong, a ship, and Dun, a town—"the town of ships." On considering the situation of London on the Thames, with its numerous tributaries taking their origin on the hills both north and south of the Thames valley, one can understand that the lands around the town were in former years dotted with springs and pools.

I may remind you of a quaint quotation taken from a translation of the "History of London," written in 1180 by William Fitzstephen, a Canterbury monk and the friend of Beckett:—

"Round the city again, and towards the North arise certain excellent springs at a small distance, whose waters are sweet, salubrious, and clear, and whose rannels murmur o'er the shining stones; amongst these Holywell (Shoreditch), Clerkenwell, an 1st Clement's Well may be esteemed the principal, as being much most frequented, both by the scholars from the school (Westmin'ster) and the youths from the city, when in a summer's evening they are disposed to take an airing."

And another quotation from the "Survey of London," by John Stowe, the English antiquary and historical writer of the sixteenth century, who, referring to the thirteenth century, says:—

"They had in every street and lane of the city divers fair wells and springs; and after this manner was this city then served with sweet and fresh waters which being since decayed, other means have been started to supply the want."

These quotations bring vividly to the imagination the existence in the early days of streams, ponds, pools, wells, and springs, not only on the north side, but on the south side in Southwark, Lambeth, and contiguous neighbourhoods. Most of the pools have been filled in and the springs and streams diverted into sewers.

Thus one knows that in very early days before Fitzstephen's and after Stowe's time there must have been no lack of facilities for bathing in the open.

The names of many streets will indicate to what extent the existence of water affected the nomenclature of the districts—e.g.: Bath-street (Newgate-street), Bayswater-road, W., Brook-green, Hammersmith.

#### Olden Baths of London.

One of the most interesting amongst the olden baths of London is the Old Roman Spring Bath (or Plunge Bath), situated near King's College, Strand, because this bath still remains as one of the few relics of Roman London. It was probably built about 2000 years ago, in the time of Titus or Vespasian. It is supplied with clear water coming from springs at Hampstead, and was considered to be the overflow from St. Clement's Holy Well in the vicinity. The bath, rounded at one end and square at the other, is in the centre of a fair-sized, solidly built, vaulted chamber, and lit by a little semicircular window. Its length is 13 ft., breadth 6 ft., and depth 4 ft. 6 in. Charles Dickens refers to this bath in "David Copperfield."

The Templars' Bath or Lord Essex's Bath. Adjoining the Roman Bath and deriving its water-supply from it was another bath, of octagonal shape, the Templars' Bath, used for three centuries by residents in the Temple and closed in 1893. It was built in 1583 by the Earl of Essex, whose house was near. The site is now covered by the larder of the Norfolk Hotel.

St. Agnes-le-Clair Bath was situated on the site now named St. Agnes-terrace, near St. Luke's Hospital, Old-street, and is considered to have been first used in 1502, being supplied by the St. Agnes-le-Clair spring (one of the holy wells of London), although a Roman origin was at one time claimed for it; for in the eighteenth century many ancient copper coins, Roman relics, and other antiquities were discovered in the bath, as well as Roman tiles. Some writers consider these were brought thither and cast into the spring as votive offerings. The spring was dedicated to St. Agnes and called "le Clair" on account of the transparency of its waters. Stowe speaks of them

<sup>1</sup> A paper read before the London Dermatological Society in an abridged form.

as "Dame Anne's the clear." An advertisement in 1758 speaks of the bath as being "much applauded by the learned physicians of old" "in rheumatic and nervous cases and headache, and for cutaneous eruptions and inflamed eyes." In 1854 the Bath House was damaged by fire and the bath came into disuse.

The Peerless Pool, Baldwin-street, City-road, behind St. Luke's Hospital, was referred to by Stowe as "one other clear water, called Perilons Pond, because divers youths by swimming therein have been drowned." It was enclosed in 1743 by Wm. Kemp, a London jeweller, who changed its name to Peerless Pool and used it as a bathing place. Fed by springs, this open-air pool measured 170 ft. in length, 108 ft. in breadth, and from 3 to 5 ft. in depth. It was nearly surrounded by trees and marble steps led to a gravel bottom, through which springs percolated. It became a favourite resort of anglers and swimmers. Peerless Pool was used as a bath until about 1850, when it was drained and built over, and its name is commemorated by Bath Buildings, Peerless-street, and Bath-street, to the north and west of St. Luke's Hospital.

The Cold Bath in the New (Euston) Road was situated near the old Adam and Eve Tea Gardens at the north-west end of Tottenham Court-road. The bath was in a pleasant garden and was supplied by a spring. The water was described as being "beneficial to persons suffering from nervous disorders and dejected spirits." It was in existence in 1785, and was then advertised as being "in fine order for the reception of ladies and gentlemen."

The Cold Bath, Clerkenwell, situated near the River Fleet, or, as it was then called, Turnmill Brook, not far from the spot where the Clerks' Well existed (near the present 18, Farringdon-street), was a cold spring which, in 1697, was converted into a bath by the owner of the surrounding property, Walter Baynes, and was described as the "most noted and first about London." The charge for bathing was 2s. or 2s. 6d. if use were made of the chair suspended from the ceiling for lowering the patient into the water. The water of the spring used for drinking and bathing was chalybeate, and was considered efficacious in the cure of "scorbutic complaints, rheumatism, chronic disorders, &c." It was also considered to "prevent and cure cold, create appetite, help digestion, and make hardy the tenderest constitutions." The bath was at the height of its reputation in 1700. The bath was enclosed in a building known as Coldbath House, surrounded by a garden with four turret summer-houses. The spring supplied 20,000 gallons daily. In 1815 most of the exterior of the bath-house was removed to make way for buildings, but the bath itself remained as late as 1870 (Macpherson). I believe there is now no trace of its existence. The neighbourhood was formerly known as Coldbath Fields.

Sun Tavern Gap, at Shadwell, marks the spot where a spring was discovered in 1745, which was puffed by D. W. Linden, M.D., in 1749, "for scorbutic and cutaneous disorders by drinking or bathing." It was used medicinally only for a short period, and was known as "Shadwell Spa"; the water was sold at the Spa House in Sun Tavern.

Queen Anne's Bath was situated at the back of the present No. 35, Endell-street, Long Acre. The waters were supplied from a copious spring containing iron, and were used for rheumatism and other disorders. It is said that Queen Anne used to bathe there; small rooms at the side used to be shown as her toilette and dressing-rooms. The bath-chamber was about 14 ft. square, with a lofty groined dome roof, and its walls inlaid with white and blue Dutch tiles of the sixteenth century.

The New Spa, Hampstead, was first mentioned in 1804 by a local practitioner, Thomas Goodwin, in a pamphlet entitled "An Account of the Neutral Saline Waters Lately Discovered at Hampstead." The water contained magnesium sulphate and a bath-house existed for the immersion of patients in the water from the spring. This "New Spa" had very little success. The site was near the present railway station of the L. & N.W. Railway.

(To be continued.)

#### COLONIAL HEALTH REPORTS.

*Uganda.*—According to the Blue-book for the year 1917-18, the population of this Protectorate is estimated at 3,360,439, including 570 Europeans and 3467 Asiatics. In 1917 the cases treated in Government hospitals and dispensaries numbered 70,236, with 967 deaths, these figures not including cases treated at the military hospitals at Entebbe, Bombo, and Gulu. The number of European officials resident was 378, among whom there occurred 359 cases of illness and 2 deaths. Of the total admissions to hospital 112 were due to malaria and 11 to dysentery; 8 European officials were invalided, bringing the total number during the last seven years to 30; the causes of invaliding were general debility, neurasthenia, tuberculosis, and neuritis. The number of cases treated at European and native Government hospitals decreased from 5679, with 20 deaths in 1916, to 4414 cases with 6 deaths in 1917. Forty-nine cases of blackwater fever were treated, of which 8 were fatal, com-

pared with 46 cases and 10 deaths in the previous year. The diseases which call for special attention in connexion with the native population are cerebro-spinal meningitis, sleeping sickness, plague, small-pox, and venereal diseases. Cases of cerebro-spinal meningitis treated in Government hospitals have risen from 4 cases with 3 deaths in 1915 to 71 cases with 42 deaths in 1916, and 469 cases with 347 deaths in 1917. Besides these numerous deaths have taken place all over the country, cases having been reported in every district except Masaka. The disease has been particularly severe in the northern and north-eastern parts of the Protectorate. It is estimated that not fewer than 5000 deaths took place from this disease in the districts of Gulu and Kitgum, whilst in the Arua District of the West Nile it is considered that 3000 natives have died from the same cause. The rapid spreading of this disease and the great number of deaths are due, first, to the abnormal collection and movements of natives for military purposes, and, secondly, to the shortage of the medical staff. Epidemics of small-pox occurred throughout the Protectorate, the Nile Districts and Lango being specially affected, and towards the end of the year the mortality was severe. Admissions of cases of plague to hospital show a decrease from 321 cases with 283 deaths in 1916 to 171 with 143 deaths in 1917, and the native returns show a slight decrease in the number of deaths compared with the previous year. The local sanitary boards are working in the various townships with good results, and anti-malarial measures improve the conditions of the more important stations.

#### THE KENSINGTON WAR HOSPITAL SUPPLY DEPOT.

THE DEPOT was registered in 1916 under the War Charities Act, and during the war has turned out over 6,000,000 articles, valued at £300,000, which have been sent to 1400 different hospitals at home and abroad. In a List of Surgical Appliances and Hospital Requisites issued (at 2s.) by the depot, among the many useful appliances may be noticed: a finger flexion glove, consisting of a leather wristlet with splint and glove attached—from each finger of the glove extends a strap which can be fastened to a button on the wristlet; a Hey Groves humerus extension splint which can also be used as a stump tractor; a simple type of wood splint for extension of the forearm; a Bowlby's slung leg splint for dressing wounds of the calf without disturbing a fractured limb. Many forms of pilons are illustrated; they can be obtained either with belts for cases of thigh amputation or with gauntlets above the knee for amputations lower down. The work of the depot is now being reconstructed to deal with civil hospitals and patients.

#### A PSYCHOLOGICAL STUDY OF THE PRISONER OF WAR.

Dr. A. L. Vischer, a citizen of a neutral country with a command of three European languages, has had a unique opportunity of visiting the great European internment camps and of investigating the mental changes—we should like to call them the metapsychoses—for which the conditions of internment are responsible. It will be realised when reading his book on Barbed Wire Disease<sup>1</sup> that he has made full use of his opportunities, and in addition has read widely in the literature produced by interned authors. If he has paid less attention to English writers than to French and German authors the deficiency has been realised and amply redeemed in the very able introductory chapter by Dr. Kinnier Wilson. There is far more than the loss of liberty to prey upon the minds of the internés. Uncertainty of the future, the loss of privacy, and nostalgia, aggravated by the restrictions in correspondence, all play their part, but above all, the authors lay emphasis on the constant menacing mockery of the barbed wire entanglements. As one of the men in Knockaloe Camp has written, "Physically the prisoner is powerless, but in spirit he gnaws incessantly at the roots of the thorny hedge."

What are the consequences which are observed to follow upon these changes in the prisoners' mental life? Their dreams, their irritabilities, their depression, the exaggeration of rumour, and the gradual starvation of libido have all been noted and recorded by Dr. Vischer, who has also inquired into the origins of these phenomena, their development, and the prospects of their elimination when the causative factors have been removed. The mental syndrome of the interné is then usefully compared with the experiences of others who in time of peace have found themselves "closely confined for an indefinite period." This is often the case with the crews of sailing vessels on long voyages, with polar and other explorers, and those who have chosen to live the monastic life. The book is suggestive rather than dogmatic and will be read with interest by all who are concerned themselves with the development of the science of abnormal psychology.

## The Goulstonian Lectures

ON

## THE SPREAD OF BACTERIAL INFECTION.

*Delivered before the Royal College of Physicians of London*By W. W. C. TOPLEY, M.A., M.D. CANTAB., F.R.C.P.,  
DIRECTOR OF INSTITUTE OF PATHOLOGY, CHARING CROSS HOSPITAL.LECTURE III.<sup>1</sup>

MR. PRESIDENT, LADIES, AND GENTLEMEN,—In the experiments recorded in my last lecture a culture of *B. Danysz* was fed to a certain number of mice, and from one of these, killed 24 hours after feeding, a second strain of the bacillus was isolated. This was fed to a further series of mice, and from the tissues of certain of the animals which died, or were killed when dying, during the course of this experiment further strains were isolated. These in their turn were fed to other batches of mice, and the process was repeated many times. The whole series of experiments lasted over about nine months.

Consideration of the results showed that two strains at least possessed, when first isolated, a greatly increased tendency to produce a fatal illness in mice when administered with food. Retesting of these strains at later periods confirmed their high pathogenicity, but indicated a gradual return to the original conditions under artificial cultivation. In many cases, however, the strain isolated from a mouse of a given experiment proved less pathogenic on being fed to other mice than the strain on which the mouse itself had been fed, and this was particularly true of those strains which were isolated from mice which were found dead. Each of the two strains which possessed especially high pathogenicity rapidly lost this characteristic on further passage carried out in this way.

In view of the interesting results which have been obtained by close serological study of different races of the same bacterial species, it seemed desirable to investigate the most divergent strains along these lines. High-titre agglutinating sera were obtained for six of these, and 48 strains of *B. Danysz* isolated during the course of these experiments were tested as regards their relative agglutinability and by cross-absorption tests. In every case the exact limit of agglutination was determined. The results failed to distinguish in any way between the strains examined.

## EXPERIMENTS WITH A VIEW OF REPRODUCING NATURAL CONDITIONS.

It is difficult to decide how far the conditions in these experiments reproduce those met with in nature. In so far as natural infection occurs by normal mice devouring their companions who have succumbed to the disease, they must be very similar. If, however, the main source of infection under natural circumstances is the consumption by normal animals of food soiled with the excreta of those which are infected, there will be additional factors which are absent in the experiments we have considered. There seems little doubt that the latter mode of infection is by far the more important, and we are therefore not justified in assuming that such results as have been obtained represent what happens when passage occurs under natural conditions. They form, however, a valuable guide in interpreting the results obtained in other experiments, in which the conditions were arranged to reproduce, as closely as possible, the sequence of events which must actually occur in the epidemic spread of disease.

In these experiments a certain number of mice were fed on a strain of *B. Danysz*. Next day they were transferred to a clean cage, and at varying periods thereafter normal mice were added to the cage. These were identified in some way, sometimes by merely noting the colour markings, sometimes by marking them with some distinctive dye. The deaths were noted as they occurred, and where possible post-mortem examinations were carried out. In some experiments several of the mice were found partially eaten. In one of them only were a certain number of dead mice left in the cage for their companions to devour. The results yielded no evidence that this factor modified the course of events in any way.

The charts in which the results of some of these experiments are shown are constructed as follows. On the upper base-line are recorded the deaths as they occurred in time. On the lower base-line are recorded the number of mice fed, the number of normal mice added, and the time at which the addition was made. The figures below the base-lines indicate days. Each square, representing a death or the addition of a normal mouse, is numbered, and the numbers correspond; so that the death of each mouse added can be traced as regards the time of its occurrence. The mice which died are represented by hatched squares in each case, so that the plain squares on the lower base-line correspond to normal mice which were added to the cage but survived.

*Results of Experiments.*

The results of one such experiment are recorded in Chart IV. Six mice were fed on a culture of *B. Danysz*. Five days later six normal mice were added to the cage. Three days later one of these was found dead. On the fourth day from this the first death occurred among the mice ordinarily fed, and one of these mice was found dead on each of the next three days. One of the mice added on the 6th day of the experiment succumbed on the 14th day and three on the 15th. On this day four more normal mice were added. One of these died three days later; the other three survived. Thus of six mice fed on this strain of the bacillus four died. Of six mice added between the date of feeding and the first death which occurred among the mice fed five died and one survived. Of four mice added on the 15th day of the experiment one died and three survived.

Chart V. shows the results of another experiment with a culture of the same strain of *B. Danysz*. It will be seen that of the eight mice fed on this culture five died. Of six normal mice added on the 7th day of the experiment, three died and three survived. Two mice were added on the 10th day, and three on the 14th. All of these survived.

Chart VI. shows a similar experiment with the original strain of *B. Danysz*. Of the eight mice originally fed four died. Three mice were added to the cage on the 14th day of the experiment. One of these died and the other two survived. Two mice were added on the 18th day, and both survived.

Thus in each of these three experiments when normal mice were added to the cage during the early stages a large proportion of them became infected and died of the disease. Mice added during the later stages, however, showed an increasing tendency to escape infection, and in some cases all the mice added at these later periods survived.

Chart VII. shows a similar experiment on a larger scale. It will be seen that it is referred to on the chart as an epidemic due to an unknown cause. The exact facts are as follows. The experiment was an attempt to ascertain whether strains of *B. Danysz*, possessing heightened pathogenicity, would be evolved as the result of natural passage, a possibility strongly suggested by the variation in this direction which had been observed in the passage experiments carried out in the manner indicated in my last lecture.

It had already been noted that mice exhibited a very definite age-susceptibility as regards infection with this organism. The experiments already considered were carried out with adult mice. When young mice were fed on the same culture an entirely different result was obtained. Thus in one experiment six young mice were fed on a 24-hour broth culture of this original strain. One was found dead next day, four on the day following, and the remaining mouse died on the 14th day.

An attempt was made to utilise this special susceptibility of young mice in the experiment under consideration. Four such mice were fed with a 24-hour broth culture of the original strain, and were transferred next day to the large cage in which this experiment was carried out. This was a long cage originally divided into 15 compartments, each of which would accommodate from two to four mice. A communication was made between each compartment, and the food was placed in a large centre compartment made by removing the two central partitions. At the time these four young mice were transferred to this cage one was obviously ill. It was found dying later the same day and was then killed and examined post mortem. Two more of these four mice were found dead on the 9th day after feeding. One was examined after death, the other was

<sup>1</sup> Lectures I. and II. were published in THE LANCET of July 5th (p. 1) and 12th (p. 45), 1919.  
No. 5003.

left in the cage to be eaten by its companions. The fourth mouse was found dead three days later, but was too decomposed for examination. Thus, two of the four original mice were examined post mortem. The cultures from one remained sterile; those from the other yielded only lactose-fermenting bacilli.

CHART IV.—Showing deaths in a cage in which were placed six mice (1) fed on a 24-hour broth culture of a strain of *B. danyasz* (3 D, 21; 9, 5), and to which two further batches of normal mice were added (2, 3).

CHART V.—Showing results of feeding eight mice (1) on culture of same strain as in previous experiment, and adding normal mice to the cage at various intervals (2, 3, 4).

CHART VI.—Showing results of feeding eight mice on a culture of *B. danyasz* (original strain) and adding normal mice.

#### Consideration of Results Shown in Chart VII.

The addition of normal mice and the deaths which occurred are sufficiently indicated in the chart. Of the 44 mice which died after being introduced to the cage 13 only were examined post mortem; most of the remaining dead mice were found almost entirely eaten, a difficulty which is particularly liable to be met with when large numbers of mice are allowed to live together. Of the 13 mice examined, seven yielded cultures of lactose-fermenting bacilli only, while the cultures from the remaining six mice remained sterile. Thus, during the course of the whole experiment *B. Danyasz* was never isolated from any of the mice examined. In five of these 13 mice, however, the spleen was considerably enlarged, in five it was slightly enlarged, while in the other three it appeared normal. The post-mortem appearances were, in fact, entirely compatible with death from a *B. Danyasz* infection, but in the entire absence of bacteriological confirmation it seems wiser to regard the cause of the epidemic as non-proven.

A point of some interest may, however, be noted. In all experiments of this kind it has been found that a most marked disproportion exists between the percentage of

recoveries of *B. Danyasz* from mice fed on cultures of this organism and from mice naturally infected through contact. Thus, while the bacillus has almost always been isolated from a considerable proportion of mice fed on cultures, other mice, dying in the same cage and during the same time interval, may yield entirely negative results. A high proportion of cultures from these mice remain sterile, while others yield lactose-fermenting organisms only. The number of mice examined so far has not been sufficient to exclude a mere chance coincidence, but the distribution of positive and negative results has been striking, and the matter is being investigated further.

Whatever the explanation may be, it does not directly concern us here. Regarding the course of events in the cage merely as a chance epidemic, the points already noted are evident again. The mice added in the early stages died. As the epidemic progressed a proportion of the newcomers survived. At a later stage, when deaths were still occurring in the cage, the risk of infection seemed to fall to a minimum, for almost all mice added at this stage survived.

#### EXPERIMENTAL EVIDENCE OF LOSS OF INFECTIVITY.

If we consider the results of these experiments one conclusion seems inevitable. Whatever part other factors may play, the cessation of the epidemic is actually due to the loss, on the part of the parasite, of the power to infect fresh individuals. It is impossible to conceive that in every experiment chance should have intervened by selecting especially resistant mice as the individuals to be added during the later stages.

Direct evidence on this point has been obtained in the following way. In the experiment recorded in Chart IV, there remained, at the time of the last death, six survivors. Twenty-three days later all these mice were alive and apparently in perfect health. On this day three normal mice were fed on a culture of the same strain of *B. Danyasz* as that employed in the original feeding and were transferred to the cage later in the day. Fifteen days later a fresh outbreak of infection occurred, which lasted for five days and led to the death of two of the three mice which had been fed and added to the cage and of three of the six survivors from the original epidemic. It seems clear, therefore, that the surviving mice were not immune against the risk of naturally occurring infection.

#### Cross-infection in regard to Epidemic Period.

The evidence of the loss of infectivity on the part of the parasite, during the later stages of the spread of a *B. Danyasz* infection among mice, finds support in certain observations on naturally occurring epidemics in man. In the paper already quoted Brownlee gives some striking figures regarding cross-infection in hospital wards from cases which were admitted for some other disease, but which were subsequently found to have been incubating measles. He has tabulated the number of such cases which did or did not lead to the infection of other patients in the ward, according as the incubating cases were admitted during the rise or decline of a measles epidemic or during an inter-epidemic period. Twenty-eight such cases were admitted during the ascent of the wave. In 24 of them cross-infection occurred. Four cases were admitted during the descent of the wave, and cross-infection occurred in two of the four. Nine cases were admitted during an inter-epidemic period, and six of these failed to give rise to cross-infection. The figures are small but highly suggestive.

It is clear that where it is possible to compare the curves of morbidity and mortality during a given epidemic the relation of these to each other will afford information bearing on this point. In certain cases where this has been done the crest of the morbidity curve has preceded, by a varying time-interval, the crest of the curve of mortality, and this is what we should expect from the considerations outlined above.

#### Virulence of Organisms.

If we inquire the cause of this loss of infectivity on the part of the virus one factor may be at once eliminated. The parasite does not cease to be infective because it is no longer virulent.

Those strains of *B. Danyasz* isolated during the course of the earlier experiments, which showed the greatest divergence as regards their ability to infect via the alimentary canal,

have been repeatedly tested as regards their virulence on intraperitoneal injection. The results have been remarkably uniform with the five strains tested. Intraperitoneal injection of 0.5 c.cm. and 0.25 c.cm. of a 24-hour broth culture has always been followed by death, usually within 24 hours. The majority of mice receiving 0.025 c.cm. have died within

MICE DIED.

MICE ADDED.

MICE SURVIVED.

MICE DIED.

CHART VII.—Showing course of epidemic, of unknown cause, occurring in a large cage to which normal mice were added at irregular intervals.

48 hours. Mice receiving 0.0025 c.cm. or 0.00025 c.cm. have usually succumbed after a more prolonged interval (4-10 days). Mice injected with 0.000025 c.cm. and 0.0000025 c.cm. have never shown any ill-effects.

Thus a strain which failed to cause the death of a single mouse within 25 days of being administered with the food, and finally led to the death of one of six mice fed, always caused death in four days when 0.00025 c.cm. of a 24-hour broth culture was inoculated intraperitoneally.

Control tests, made with killed broth cultures to allow for the element of toxicity, sometimes produced late death (5-10 days) when 0.5 c.cm. of a killed culture was injected. Smaller quantities produced no apparent effect.

The question as to whether the especially infective strains were also more than usually virulent cannot be answered satisfactorily from the results of these tests. In some cases the virulence tests were not carried out for some time after the isolation of the strain. Although there was still a definite difference in the effects produced by feeding at the time when the virulence of the strains was tested, yet it was not so marked as at the time of isolation. The fact which emerges clearly is that an almost completely non-infective strain—that is, one which produces no illness when taken with the food—may be fully virulent when inoculated into the peritoneal cavity.

#### Cause of Loss of Infectivity.

To what, then, are we to ascribe the loss of infectivity on the part of the parasite? It must clearly be due to some deficiency which hinders it in its passage from host to host. Its power for multiplication in the tissues in general is not lessened. It seems at least possible that it is the power for multiplication elsewhere that is at fault.

Danysz, as noted above, has suggested that increased virulence for the tissues resulting from passage by subcutaneous injection or in some other way results in a loss of virulence in the alimentary canal. It is probable that in the spread of bacterial infection the parasite actually passes through successive phases of biological activity. It must live and multiply under very varying conditions. In an infected host it is living as a true tissue-parasite. If it be transferred to the naso-pharynx or to the alimentary canal of a fresh individual of the host species, it must be able to accommodate itself to the new conditions. For in the absence of active multiplication it is highly unlikely that successful tissue invasion will be brought about. If the parasite is to be conveyed from host to host by a biting insect, then it must face the change in environment from the tissues and blood stream of the host to the alimentary canal of the insect carrier.

Indeed, it is probably the fact that during the spread of infection the parasite is subjected to a regular succession of environmental changes. Failure of accommodation at any stage may clearly prevent the infection of a fresh host. Now there is abundant evidence that adaptation to a new environment may be associated with a lessened ability to thrive under the old conditions. If the origin and rise of an epidemic wave do indeed depend on the factors which have been considered in the earlier part of these lectures, there seems to be an adequate reason for believing that continued variation of the parasite in the same direction would lead to the decline of the wave.

#### The Possible Course of the Process.

It was suggested that a saprophytic spread of the micro-organism concerned, associated with an increasing ability to multiply rapidly under the conditions locally existing, might form the earlier stages of the process. Reasons were given for believing that this increase in the rate of multiplication would itself tend to increase the probability of successful tissue-invasion and that successful transference to new hosts might lead to the natural selection of strains or varieties possessing increased powers of multiplication within the tissues—that is, increased virulence.

It would consort well with all our knowledge on such matters if a gradual increase in virulence were associated with a gradual loss of the ability to live under the earlier saprophytic conditions. We should thus have a loss of infectivity, unassociated with a loss of general virulence. The combination of biological attributes which the experimental results seem to require.

Whether or no bacterial parasites pass through developmental cycles, similar to those known to occur in other living organisms, is a question which has still to be answered. It would seem, however, that the essential phenomenon of an epidemic may be the progress of the virus through a cycle of selective variations which must be retraversed in each successive wave.

The accompanying diagram indicates roughly the possible course of such a process. The line indicating the variation in the rate of multiplication as a saprophyte must be taken to represent the degree of adaptation for life in the naso-pharynx or in the alimentary canal of the host or in the body of some insect carrier. It should almost certainly be represented not as one line but as a whole series of curves, corresponding to successive environmental changes. In the

Diagram indicating possible explanation of the acquirement and loss by a bacterial virus of the property of infectivity during the course of an epidemic. The continuous line in the rate of growth as saprophyte and the broken line rate of growth as "tissue-parasite" (virulence). A-B, period of "infectivity" and duration of epidemic.

same way the curve indicating variation in the rate of multiplication in the tissues represents the degree of adaptation for life under these very different conditions.

The increase in the rate of saprophytic growth is followed after a time by a gradual increase in the rate of parasitic growth in the strains successively evolved; but at some point in the rise of the latter curve, the curve of true virulence, there commences an associated fall in the curve representing the potentiality of saprophytic existence. It is during the period in which both these curves are at an abnormally high level that the parasite possesses infectivity, and it is during this same period that the epidemic occurs.

It has already been noted that, in an outbreak of cerebrospinal fever, the carrier-rate begins to fall while the epidemic is at its height. Here, again, we have an indication of a loss of capacity for saprophytic growth in an increasingly virulent parasite preceding the decline of a wave of disease.

#### *Capacity of Bacterial Parasites for Variation.*

It might, perhaps, be supposed that the acceptance of such a view as this would involve the belief that any bacterial parasite, given the requisite environmental conditions, might give rise to epidemic disease. Neither clinical nor bacteriological experience would, however, lend any support to such a view. The constancy of the characteristic features of a given epidemic disease, when viewed as a whole, strongly indicates a uniform and specific virus. The results of countless attempts to increase the virulence of different bacteria have shown conclusively that while with some species this may be done with certainty, with others the most prolonged efforts in this direction have proved entirely fruitless.

It would seem that we are dealing with a more or less specific capacity for variation, analogous to the acquired capacity for bringing about certain fermentations, which has been studied by Penfold and others. As the result of certain environmental changes the bacterial parasite will vary in a particular direction, but the ability to react in this way must be regarded as something inherent in the organism itself.

#### THE SELECTIVE LOCALISATION OF BACTERIA.

Recent work on the selective localisation of bacterial parasites, and especially of members of the streptococcal group, has afforded evidence which has an important bearing on the point at issue.

Rosenow, in several communications, has dealt in detail with this matter. He has found that strains of streptococci, isolated from particular lesions in man, have tended to produce a high percentage of lesions in the same tissues or organs when inoculated intravenously into rabbits.

One example, which is of particular interest from the point of view of progressive adaptation to life in different tissues, may be referred to in more detail. Rosenow found that strains of streptococci isolated from cases of appendicitis, gastric ulcer, and cholecystitis resembled one another very closely in cultural and other ways. He found also that the general virulence was greater in strains isolated from gastric ulcer than in those isolated from appendicitis, and greater still in strains isolated from cholecystitis. The table shows the results he obtained by the intravenous inoculation of such strains at the time of isolation, after prolonged cultivation, and after passage.

Table showing Elective Localisation of Streptococci Obtained from Various Sources when First Isolated after Cultivation on Artificial Media and After Passage.

Nature of case from which streptococci were isolated.	No of strains examined.	No. of animals inoculated.	Percentage of animals showing lesions of—				
			Appendix.	Stomach and duodenum.		Gall-bladder.	Pancreas.
				Hæmorrhage.	Ulcer.		
Appendicitis—							
When isolated ...	14	63	63	7	1	1	0
Later ...	8	26	15	19	15	4	0
After passage ...	7	22	45	45	30	40	0
Ulcer of stomach—							
When isolated ...	13	103	3	60	60	20	3
Later ...	8	22	5	5	0	5	0
After passage ...	7	39	0	23	33	30	15
Cholecystitis—							
When isolated ...	12	41	0	39	15	80	5
Later ...	5	14	14	28	14	7	0
After passage ...	4	16	0	31	13	56	19

The above table is taken from the data given by Rosenow in a paper on "The Elective Localisation of Streptococci."

#### *Some Significant Facts.*

Several most significant facts can be observed. At the time of isolation the appendix strains seldom gave rise to lesions of the stomach or gall-bladder in the rabbits inocu-

lated with them. After passage they caused a considerable percentage of lesions of these organs among the rabbits inoculated, while there was a slight decrease in the percentage of appendicular lesions produced.

The strains obtained from cases of ulcer of the stomach or duodenum, when first isolated, produced a high percentage of lesions of these organs, but very few lesions of the appendix. The relative number of gall-bladder lesions produced was considerably higher than with recently isolated strains from appendicitis. After artificial cultivation, when some loss of general virulence might be expected to have occurred, the proportion of appendicular lesions produced by the gastric and duodenal strains was slightly raised, but the proportion of lesions of the stomach, duodenum, and gall-bladder was considerably lowered. After passage the percentage of lesions in the appendix, stomach, and duodenum was less than at the time of isolation, but the proportion of rabbits showing gall-bladder lesions was raised.

Similarly the strains isolated from cases of cholecystitis caused no appendicular lesions, but a considerable proportion of lesions of the stomach and duodenum and a very high percentage of lesions of the gall-bladder. Artificial cultivation resulted in a loss of the power of affecting the gall-bladder, but an increase in the tendency to localisation in the appendix. Passage resulted in little change so far as these three organs were concerned.

The production of lesions of the pancreas by these strains is particularly interesting. No appendicular strain affected this organ. Three per cent. of the rabbits inoculated with strains from the stomach and duodenum showed pancreatic lesions. After artificial cultivation none did so. After passage 15 per cent. of rabbits showed lesions in this organ. With the gall-bladder strains lesions of the pancreas were produced in 5 per cent. of the rabbits inoculated with the cultures when first isolated. After artificial cultivation this property seemed to be entirely lost. After passage the proportion of pancreatic lesions was raised to 19 per cent.

Clinical observation, indeed, yields abundant evidence of the tendency for certain organisms to produce lesions in definite tissues. Moreover, the changes in type of a given disease during the course of an epidemic, and in successive epidemic waves, strongly suggests progressive adaptation on the part of the parasite to life in different tissues.

#### RESISTANCE OF THE HOST.

Though reasons have been given for believing that the outstanding feature in the subsidence of an epidemic is a loss of infectivity by the bacterial virus, yet the resistance of the host cannot be a negligible factor. It will operate by decreasing the concentration of susceptible individuals, and hence the chances of successful transference. It may clearly play an important part in contributing as an environmental factor to the progressive variation of the parasite.

There is no sufficient evidence as yet to enable us to form an opinion as to the exact way in which this factor of immunity, or the opposite condition of sensitisation, may affect the whole process. Probably they play a most important part, but the fact remains that the virus itself is ultimately altered in such a way that it can no longer infect normal individuals of the host-species, and this must be regarded as the essential point.

Similarly, the factor of bacterial symbiosis is probably of the highest importance, but here, again, we must wait for more exact knowledge.

#### VARIATION OF PARASITE DURING AN INDIVIDUAL ATTACK AND DURING COURSE OF EPIDEMIC.

It is of considerable interest to compare the changes in the biological characteristics of the parasite during a single attack of disease with the variations which occur during the whole course of an epidemic. The results recorded by Danysz, and the confirmatory evidence obtained in the present experiments, make it clear that strains of the bacillus isolated during the earlier stages of the disease, or before death, are far more likely to be infective to other mice than strains isolated after death—a fact which may probably be interpreted in the same way as the loss of infectivity during the decline of an epidemic.

There is a very general consensus of opinion that many infectious diseases exhibit their maximum infectivity during the earlier stages of an attack. Conradi has attempted to trace the period of infection, as regards the stage of disease in the infecting case, in 85 contact cases of typhoid fever.

According to the figures he obtained it appeared that 49 of these 85 secondary cases were infected during the first week of the primary case, 16 during the second week, and 10 during the third.

Klinger analysed 812 contact cases in a similar manner. He arrived at the conclusion that 33 of these cases were infected during the first week of the incubation period of the primary case, which was taken to be 14 days, while 150 were infected during the second week of this period. Thus, 183 secondary cases were the result of infection during a period when the patients forming the primary cases were not obviously ill, but when they must have been excreting the specific organism. The figures for contact cases traceable to infection during the first four weeks of the infecting case were 187, 158, 116, and 59 respectively. Klinger's figures thus corroborate those given by Conradi, with the additional suggestion of the importance of the incubation period from this point of view.

A very recent communication by Thomson, relating to cross-infection in a hospital ward in the case of chicken-pox, records observations which suggest that the contact infectivity of this disease undergoes a marked decrease about the end of the first week of the eruption.

Here again, then, clinical and epidemiological evidence supports, and is supported by, that obtained along bacteriological lines. It would seem that the cycle of variation passed through by the parasite during an isolated attack of disease is very similar to that traversed by the same bacterial virus during an epidemic wave.

#### THE INTER-EPIDEMIC PERIOD.

If this conception of the epidemic spread of bacterial infection be the true one, it may be inquired whether it throws any light on the long epidemic-free intervals in some cases, and the periodicity of the outbreaks in others. The subject is far too large and too complex to be considered here in any but the briefest and most tentative way; but certain consequences would arise from such a process which seem to offer a possible explanation of some of the phenomena observed.

The process, viewed from the standpoint of the bacterium, has been conceived as a progressive variation in the direction of adaptation to increasingly parasitic conditions of life. But the virulent variety evolved, so well adapted for its parasitic rôle, will have become so ill suited to life outside the body, and especially to life under those special conditions which have to be faced on the way to successful infection of a new host, that it will gradually die out from mere inability to secure for itself those environmental conditions which are necessary for its continued propagation.

Thus, at the end of such a cycle we should be left with scattered centres in which the virus was still existing in some earlier phase, but in order to produce a fresh wave of disease the whole of the latter part of the cycle must be passed through afresh. Now it has been seen already that the essential condition for such a process is a sufficient concentration of susceptible individuals, a factor whose importance in initiating epidemics has been emphasised by many epidemiologists, such as Farr, Davidson, and Hamer. This condition will clearly not exist if the epidemic has been a large one, for a considerable proportion of the population will have had conferred upon them an increased degree of resistance.

The length of the inter-epidemic period will depend on many factors: the extent of the epidemic, and hence the relative number of the population possessing heightened resistance; the natural persistence of such acquired immunity, which we know to vary with different diseases; and such factors as age susceptibility, which may involve long periods of time before a sufficient concentration of susceptibles is obtained for the start of another cycle of variation.

One fact must be emphasised. A degree of immunity quite insufficient to protect against a highly infective virus—that is to say, against an attack of the disease during an epidemic period—may well be sufficient to hinder or prevent those earlier transferences which form an essential part of the process.

If the inter-epidemic period be a long one the centres of increased prevalence of the specific virus will certainly have diminished in number and extent, and it may need special environmental conditions, such as the increased over-

crowding and increased migration which war involves, to start the cycle again.

#### SECONDARY EPIDEMIC WAVES.

In a completely stationary population it would be difficult to fit the occurrence of secondary epidemic waves into such a conception as that here outlined. Under modern conditions, however, such stationary populations do not occur in big cities. If there be a steady influx of new individuals secondary waves are less difficult to account for. Fresh susceptibles arriving at the epidemic centre during the rise and crest of the wave will probably fall ready victims. As the wave subsides, however, these fresh arrivals will tend to escape, and they will be so diluted by the immune population that they will not form a soil suitably distributed for the start of a fresh cycle.

We may suppose that there will be a gradual reaccumulation of a susceptible population; but although this may reach a sufficient density to allow of the propagation of a second wave of disease, yet it will probably never equal that initially existing. Hence the rise of the wave will probably be less steep and sudden, and the crest flatter, than in the primary wave. These features actually occur, as has been pointed out by Greenwood and others, in the case of influenza.

#### *Influenza.*

In the case of this disease, at least, there is a definite increase in mortality during the secondary wave. It is possible that one factor contributing to this is the presence, scattered among the community, of strains of the virus which already possess in some degree those attributes which go to make up infectivity. If the new cycle of variation were to progress from this relatively advanced phase, and the spread of infection were to radiate from many scattered centres, it would seem probable that an unusually large proportion of highly virulent strains would make their appearance before the final phase was reached and before the loss of infectivity caused the subsidence of the wave.

The interval between the primary and secondary waves, and, indeed, the very occurrence of the latter, will depend on the rate of the influx of the fresh population—that is, largely on the ease of transit and the circumstances which may render migration abnormally great or small. There seems here a possible explanation of the variation observed in successive epidemics of influenza.

The solitary epidemic of 1847-48, the period 1889-94, with its four waves separated by relatively long intervals of time, and the present visitation, with the rapid sequence of primary and secondary waves, followed after another short interval by a third, correspond with the increase in the ease and rapidity of transit which has occurred during the same period, and hence with the rapidity with which a relatively susceptible population will tend to reaccumulate in an affected district. During the past months there have been many additional factors tending to an enormous increase in migration, leading to the same result.

#### THE CARRIER PROBLEM.

Assuming that the epidemic spread of bacterial infection follows the lines indicated above, we may inquire how far it may affect our conception of the rôle of the human carrier.

#### *Temporary Carriers.*

Carriers, as we have seen, may be divided into two fairly well-defined classes, according as they carry the specific organism concerned over short or prolonged periods. The latter type of carrier is in a very small minority and often exhibits peculiarities which appear to predispose to the carrier state.

The temporary carriers may again be subdivided according as they have or have not recently passed through an attack of the disease in question. Of these two varieties of temporary carriers we should seem to be justified in paying relatively slight regard to those individuals who have recently recovered from an attack, so far at least as they may be supposed to constitute important sources of immediate infection. Experimental and clinical evidence indicates that in such late stages of the disease the infectivity of the virus is at a minimum. The danger of these temporary carriers lies rather in the possibility that they may develop into the chronic variety.

Temporary carriers who have not passed through a recent attack would have to be regarded as manifestations of a general biological process leading up to an outbreak of disease.

Experience does not support any expectation that it would be possible to eliminate such carriers from the general population during the pre-epidemic stage by any method which would be practicable from an administrative point of view, save, perhaps, under special local conditions. The discovery of a rise in the carrier-rate of such an organism as the Meningococcus may, however, constitute a most useful warning of the imminence of an epidemic, and lead to the putting into force of those preventive measures whose efficacy has been proved.

#### *Chronic Carriers.*

The chronic carrier is a far more difficult problem. His importance as a possible centre for the spread of fresh infection has been abundantly demonstrated, in the case of typhoid fever at least. Whatever attempt may be made to minimise the part played by certain notorious carriers, it is difficult to believe that impartial judgment can give any other verdict on the whole facts. The case of "Typhoid Mary," of American fame, may leave room for doubt; but there are so many classical instances, including such convincing cases as that of the Folkestone milker, that the potential infectivity of carriers of this kind would seem to be clearly demonstrated.

There are two ways in which we might hope to prevent the harmful activities of such individuals. By rigorous bacteriological examination it might be possible to detect those persons who continue to carry the specific organism from the actual attack onwards. Such a scheme, however, presents difficulties so formidable as to exclude its actual enforcement. The control which it would be necessary to exercise over the movements of convalescent patients would hardly be submitted to. The possibilities of evasion by presenting false specimens for examination would be infinite in many cases. Moreover, the marked intermittency of the excretion of the specific organism suggests that no measure of control, short of repeated bacteriological examination lasting over many years, would avail to eliminate all these unfortunate individuals.

Our knowledge of the infectivity of the chronic carrier may, however, be utilised in another way, which offers far greater hope of useful results. If the possibility of this source of infection be constantly kept in mind in investigating epidemics of disease, then we may sometimes trace the trouble to its source, and by controlling the movements of the carrier prevent further infections occurring. The possibility of the control of the movements and activities of a proved chronic carrier is, of course, a purely legislative and administrative problem.

Consideration of the famous typhoid carriers strongly suggests that their occupation is a matter of primary importance. Nearly all have been in some way directly concerned in the handling of food and drink. Limitation in the direction of preventing them engaging in work of this kind would probably reduce their potential infectivity to a minimum.

Another fact seems worthy of notice. The chronic typhoid carrier does not seem, in most cases, to form the starting point of an epidemic spread of infection in the sense considered above. He seems rather to pass on to his victims, through the medium of food or drink, fully infective bacilli. Moreover, his activities in this direction are strikingly intermittent. It seems possible that the bacilli which he is harbouring in his alimentary canal or elsewhere are of a low degree of infectivity, but that at intervals some environmental change leads to variation in the direction of an increase of this attribute, and that it is under these circumstances that infection of other individuals occurs.

The experimental and the clinical results recorded, and especially those obtained by Rosenow, would suggest that it is not only in the spread of infection from case to case, but in the progressive involvement of different tissues in the same patient that variation in the biological activities of the parasite may form an essential factor. The progressive involvement of tissues in such a disease as tuberculosis might be largely explained on such a view.

#### THE POSSIBLE PREVENTION OF EPIDEMIC SPREAD OF INFECTION.

If only we had the requisite knowledge as regards the causative organisms of the more important infective diseases, and could establish a systematic survey of the bacterial flora of representative samples of the population, it would seem

that we might obtain warning of the approach of an epidemic during the early stages of the process and before the actual commencement of the wave of disease. If this were possible there seems some ground for hope that something could be done to check the process in its earlier stages. In normal times, when considerations of public health are not overruled by still more urgent necessities, it should not be impossible so to alter the environmental conditions that serious obstacles would be placed in the way of the continued variation of the virus.

Information is needed on many points. The normal bacteriology of such an important locality as the nasopharynx is not known with any exactitude. Modern serological methods have placed at our disposal an instrument for the more exact differentiation of bacterial types which should prove of the greatest service in any such inquiry. If any work along such lines as these is to bear fruitful results, uniformity of technique among the observers engaged upon it is an essential factor. The work already carried out by the Medical Research Committee gives good ground for the belief that much that has proved impossible in the past will be attainable in the future.

The factors which tend to render the host-species more susceptible to attack, and especially the effect of such relatively simple matters as differences in temperature, atmospheric moisture, &c., are still very imperfectly understood. The observations of Leonard Hill offer an example of the valuable information which may be obtained by work along these lines.

The success of prophylactic inoculation in preventing the spread of epidemic infection has been amply demonstrated in certain diseases. Experience would suggest that it is in the prevention rather than in the treatment of disease that bacterial vaccines will find their permanent place. It seems possible that they may act largely by decreasing that concentration of susceptible individuals which is an essential factor during the earlier stages of the spread of infection. As pointed out above, a degree of resistance quite ineffective against a highly infective parasite might be of decisive importance at this stage.

Although the facts recorded above, when considered as a whole, would appear to be most satisfactorily explained along the lines indicated, the problem must be finally solved in the light of further evidence accumulated from all possible sources. It is only by the combined efforts of all workers in this field of biology that we are likely to acquire that knowledge which is so important for the prevention of disease.

The inquiry can clearly be extended on the experimental side. Further work along these and similar lines is being carried out in my own laboratory. There seems no reason why many of the conclusions arrived at through biometrical investigations should not be tested by experiments of this kind.

I should wish to record my indebtedness to Dr. Arkwright for supplying me with cultures and sera; and to Dr. Leiper and Professor Blackman for the benefit of their opinion on certain points. I am also indebted to Dr. S. G. Platts for much assistance during the earlier part of these investigations, and very especially to Mrs. Phyllis Worthington and to Dr. M. A. Omar for their constant help during many months.

**CORNWALL MEDICAL CHARITIES.**—At the recent meeting of the Committee of the King Edward VII. Memorial Fund (Cornwall), which was held at Truro, the sum of £170 was allocated to various Cornish medical institutions.

**SOMERSET COUNTY COUNCIL AND TUBERCULOSIS.**—The Tuberculosis Subcommittee of the Somerset County Council recommended the purchase of 135 acres of land at Lincombe Hill, near Weston-super-Mare, for the provision of a permanent tuberculosis sanatorium, and this has been adopted by the council. The price of the land was £3250.

## CEREBRO-SPINAL FEVER.

REMARKS ON ITS EPIDEMIOLOGY, PREVENTION, AND CLINICAL FEATURES.

By J. DORGAN, M.B. R.U.I., D.P.H., D.T.M.,

LIEUTENANT COLONEL, R.A.M.C.

THIS article is written to bring forward for criticism and inquiry a somewhat new aspect of the epidemiology and prevention and clinical features of cerebro-spinal fever. It is based on the investigation, by the writer and other officers, of an epidemic at a large X Garrison in March, 1916. A full report was submitted at the time to Surgeon-Colonel R. J. Reece, C.B., who with Lieutenant-Colonel M. H. Gordon, C.M.G., has controlled the investigation and preventive measures regarding this disease in the United Kingdom for the past four years. Further confirmatory facts have since been brought to the notice of these officers in official reports, letters, and verbal discussions.

The revised system of prophylaxis for 1918<sup>1</sup> has recently reached the writer in Mesopotamia. It is noted that the principal recommendations embody, without comment, the lines of prevention which were urged in the report of 1916, and which had been repeatedly pleaded for during the intervening two years.

*Circumstances in which the Investigation was Carried Out.*

The writer was employed in March, 1916, in coördinating the investigation and prevention of a large epidemic at X Garrison, having been detailed by the War Office, on the request of Colonel Reece for the services of a regular R.A.M.C. officer with special military sanitary experience. Further investigation was afterwards carried out at certain other stations, and in April, 1917, the writer had the advantage of further study at the Central Cerebro-spinal Fever Laboratory, whilst doing duty there for a short time.

The following officers were associated with the writer at X Garrison, Professor C. Samut, Temporary Captain, R.A.M.C., assisted by Captain Walter Scott, was responsible for the bacteriological investigation of the patients. His report at the time contained much that was original and interesting, and much of it has since been confirmed by other workers. Captains R. R. Armstrong and Napier were detached from the Central Cerebro-spinal Fever Laboratory. Their work was in connexion with the search for carriers. At the end of the epidemic Captain W. J. Tulloch continued their work on the carriers then in isolation. He was also detailed by Colonel Gordon from the Central Laboratory staff. Captains S. Trevor Davies and E. G. Pringle were specially selected to undertake the clinical charge of patients, and in their reports had given full details of the clinical aspects of the disease, with particular reference to atypical and irregular cases.

The report presented by the writer at the close of the epidemic included reports on the special subjects dealt with by the other officers. It is regretted that it was not possible to publish the full report at that time or later. Permission was obtained to publish an article in June, 1917, written on the same lines, but a hurried departure on active service left the arrangements incomplete. This is now written in mid-summer in Mesopotamia, under the disadvantage that the deductions of the 1918 season are unknown to the writer. Yet it is confidently believed that the views expressed in 1916 as a result of well-considered evidence, will be confirmed, rather than refuted, by the experience of yet another year.

The conclusions of the 1916 report were as follows:— I. The prevalence of atypical and unrecognised forms of cerebro-spinal fever. II. The prime importance of these atypical forms in the spread of the disease. III. There is no evidence at X Garrison to show that carriers convey active infection. The statistics as to carriers are conflicting and inconclusive, and their isolation is impracticable, irrational, and unjustifiable. IV. The infection in cerebro-spinal fever is not to be feared under good conditions of housing and ventilation. The early isolation of mild and severe cases, and the provision of free ventilation, compulsorily, and with sufficient warmth, during the time of seasonal prevalence, constitute the most effective means of prevention.

<sup>1</sup> R.A.M.C. Journal, January, 1918.*I. The Prevalence of Atypical and Usually Unrecognised Forms of Cerebro-spinal Fever.*

At an early stage of the epidemic attention became directed to the close relationship between patients definitely diagnosed cerebro-spinal fever and certain other patients suffering from indefinite febrile symptoms. The difference between the two forms of illness is in the degree and intensity rather than in the fundamental characters of the symptoms. As a rule, the symptoms of the indefinite illness were comparatively mild and commonplace, and such as, to an ordinary observer when taken individually and in the absence of an epidemic, would not necessarily suggest meningitis. Intense headache, more or less pain and stiffness of back and neck, vomiting, and insomnia were always complained of. The patient was apathetic and drowsy; he answered questions, but rarely enlarged on his symptoms, and evidently preferred to be left quiet and alone. On closer examination Kernig's sign was more or less positive; attempts to move the neck caused distinct pain, the pulse was slow, and other signs were often to be found denoting cerebral irritation. After a few days' fever the symptoms usually subsided, the patient was left prostrate, and convalescence was slow. Relapses were liable to occur, which sometimes assumed the characteristic form of cerebro-spinal fever.

At times an acute and fatal illness was associated with the proved cases, the symptoms of which were more or less obscure when critically examined. Such patients were often brought to hospital in a drowsy or delirious condition. A very acute and oedematous form of bronchitis or bronchopneumonia often quickly supervened, and death occurred rapidly with signs of septic intoxication. Various symptomatic diagnoses were made of such cases, and the cause of death was variously given—influenza, bronchitis, bronchopneumonia, asthma, pneumonia, being the most common diseases registered.

It was decided, therefore, to test such obscure cases found in association with the genuine disease. Meningococci were found in the spinal fluids of many patients whose symptoms would not have ordinarily suggested meningitis. We had reasons, moreover, for believing that many of our negative results were due to the failure of modern technique to demonstrate the meningococcus.

Suspicion was at first aroused as to a relationship between the above types of illness, not only by the similarity of the symptoms, but also by the manner in which they were found associated in billets, tents, barrack rooms, and regiments. It is impossible to give details of the numerous instances investigated by the writer where the evidence definitely pointed to the conclusion that both conditions were but variations of a single disease.

Convenient illustrations of atypical and unrecognised cases are, however, given on p. 58 of the Medical Research Committee's Report, Series 3. Captain M. Flack, of the Central Cerebro-spinal Fever Laboratory, has, however, mentioned them here as his examples of infection by carriers. This point will be discussed later.

*Some Circumstantial Evidence.*

In the first family the father, a soldier, was definitely ill, with headache and pain in the back, on his arrival home on leave. Two days afterwards one of his children was taken to a general hospital with symptoms of cerebro-spinal fever. Next day another child was taken to an isolation hospital and died of cerebro-spinal fever. The first child was discharged from the general hospital in a few days, the symptoms having aborted, being brought home by an elder sister on a Thursday. The latter died of fulminating cerebro-spinal fever which developed on the Sunday following, she having evidently been infected by the unrecognised disease in the younger member of the family.

In the second family a child was taken ill and died next day of cerebro-spinal fever. Three other children were taken ill with fever. One of them who had no marked meningitic symptoms, and in whom the blood and spinal fluid were apparently sterile, yet was subsequently accidentally found to have suffered from cerebro-spinal fever by the finding of the meningococcus in the fluid of a swollen knee-joint. The diagnosis of the other two children is, however, not given. All three are known to have been treated in the isolation hospital.

The following story was told to the writer by a soldier who came to be swabbed at the Central Cerebro-spinal Fever

Laboratory. He recently had suffered from a severe attack of so-called influenza whilst with his regiment. He was, however, only detained in hospital for three days and then got week-end leave home. He described his illness as being very severe and as "absolutely flattening him out." He suffered from headache, backache, and vomiting. Three days after his arrival home, his child developed cerebro-spinal fever, and on the following day his wife took very ill with influenza. He believed he caused her illness, her symptoms being very much the same as his own, although she was confined to bed for 14 days, attended by a doctor. His unit was infected with cerebro-spinal fever; there were no others in the family and they had little outside communication with other persons, and he proved not to be a carrier.

#### Statistical Data.

Instead of further repetition of suchlike circumstantial evidence, which came to our notice at X and other garrisons, it is proposed to argue the relationship, from statistics and facts showing the proportionate incidence of cerebro-spinal fever and possibly unrecognised forms of the same disease, in various units and stations. These statistics show that in connexion with each outbreak there is a coincident and proportionate outburst of cases of pyrexia of uncertain origin, the symptoms of which are compatible with those found in cerebro-spinal fever.

In O Block barrack building at X Garrison there were nine diagnosed cases of cerebro-spinal fever (three fatal) in March, 1916. About 120 men occupied the six rooms and comprised a half company. In addition, there were 18 other men admitted to hospital during the month suffering from febrile symptoms. Three of these also died, four others were punctured, having definite meningitic symptoms. Three others were mentioned as having been swabbed as a preliminary to puncture, and in fact, in the light of after knowledge, they all might have been cases of cerebro-spinal fever. There were 13 cases of cerebro-spinal fever in this battalion as compared with nine in this half company, and the latter's admissions for indefinite pyrexias were likewise disproportionate to the admissions for such illness for the rest of the battalion.

The writer had an opportunity of studying an outbreak which had just concluded at H Garrison in 1916. Twenty cases had been recorded. The question whether there had been unrecognised cases was the special subject of inquiry at this station. The medical officers reported a very severe outbreak of influenzal illness, chiefly localised in certain units. Many obscure deaths had occurred. The nursing sisters' report books at the Central Hospital were examined by the writer, and in this way a fairly accurate clinical picture was obtained of the symptoms of the patients. Case-sheets were available in certain cases. The names of 40 persons were thus selected as being possibly cases of cerebro-spinal fever, the symptoms being more or less suggestive.

When the names were afterwards allocated to their units the result was remarkable, and is given below in graphic form. (Fig. 1.) It shows that the units chiefly infected

FIG. 1.

with cerebro-spinal fever were infected proportionately with an illness, the symptoms of which were in close accord with the symptoms of the definite disease. Certain units were free from both forms of illness. The 40 names were selected as most suspicious from amongst the names of some hundreds of admissions during the same period. The chief symptoms which influenced the selection of these names were—severity of headache, backache, rigidity, vomiting, and delirium.

The rapid death of an otherwise healthy soldier, without definite cause, was in itself a sufficient reason for suspicion in certain fatal cases. In others, the prolongation and irregularity of the fever, with relapses and slow convalescence, seemed more in accordance with the signs of meningococcal infection than with any other definite known disease. In many of these the possibility of cerebro-spinal fever was mentioned, and sometimes lumbar puncture was performed with negative results.

From the proportionate incidence of proved cases of cerebro-spinal fever and probable and possible cases, the inference is justified that at this station the disease was more widespread than indicated by the reported cases.

At D Garrison there were 21 cases with 10 deaths. Twelve of the cases occurred in one battalion, the strength of which was one-ninth part of the strength of the whole garrison. All the cases occurred between March 15th and April 6th. The infection was imported by a draft which arrived on March 10th. In addition to the 12 cases of cerebro-spinal fever in this unit, there were 12 other persons who died from various febrile conditions amongst patients admitted during the above infective period, the symptoms again being compatible with cerebro-spinal fever. The remaining eight-ninths of the garrison had only four such deaths from febrile diseases. This extraordinarily high death rate in this battalion during the infective period is most remarkable, especially as the unit was at other times healthy, and for the periods of six weeks before and after this period it had only 1 febrile death out of 24 for the rest of the garrison. Again, there were 18 patients punctured at this station with negative results; of these, 12 belonged to the highly infected battalion, and 4 of these 12 died.

It seems undoubted, therefore, that in this battalion many persons died of cerebro-spinal fever in addition to those returned as such, and that many of those suspected cases which were punctured but which failed to receive bacteriological confirmation were in reality suffering from the disease.

At X Depot there were 20 cases, variously distributed amongst four out of the five regiments stationed there. The medical officer in charge informed the writer that there were large numbers suffering from a severe type of influenzal disease in the hospital about the same time, many of which had symptoms which approximated to those of cerebro-spinal fever. He kindly collected for me the numbers of such patients admitted per 1000 of strength. This, with the case-incidence, is given below for each regiment, and it is noticed that they are in correspondence. (The carrier percentage is, however, in the reverse ratio of the cases.)

Units	A	B	C	D	E
Cases C.S.F.	7	7	4	2	0
Uncertain pyrexia per 1000	117	92	42	28	20
Carrier percentage	22	30	24	42	35

#### Causes of Non-recognition of Cases.

Many cases of cerebro-spinal fever escape recognition because: (a) they are not suspected clinically; (b) they fail to be tested by lumbar puncture; (c) modern bacteriological methods frequently fail to demonstrate meningococci, particularly in early and irregular cases.

(a) Many cases are not suspected clinically, as mentioned, when taken individually, and in the absence of an epidemic. The laboratory at X Garrison dealt with a large area of country, in addition to the garrison, which was under our immediate observation. All the patients whom we investigated were either of the acute fulminating type or else had been ill for several days or weeks before the possibility of cerebro-spinal fever arose. Whilst working at the Central Laboratory in May, 1917, the writer visited with Captain Glover seven definitely proved cases of cerebro-spinal fever. Four of these had been for long periods under observation in well-known London hospitals before an appeal was made to the Central Laboratory. Two of them had been invalided from France as unrecognised cases.

(b) Many suspected cases fail to be tested by lumbar puncture. Often facilities for puncture are not immediately available. Lumbar puncture is regarded by many as a serious operation, and as such is only performed when the symptoms are most definite and persistent. It often happens that symptoms, which are at first characteristic, subside rapidly, and before time has been found to perform lumbar puncture the whole clinical picture has altered and puncture is not performed.

Numerous instances occurred at the stations investigated by the writer, where it was mentioned in the notes of the irregular type of patients that the question of performing lumbar puncture was considered, but for one reason or another it was not performed. The failure to puncture must occur much more frequently in civil practice and in sporadic cases, where each patient is not under particular observation.

It may be here mentioned that at X Garrison in 1916 and 1917 there were 1000 lumbar punctures performed by Captains Trevor Davies, Pringle, and Scott. There were no untoward results. The benefit to the patient from lumbar puncture alone is undoubted. No definite opinion was formed as to the benefit or otherwise of serum. A group of patients, to whom no serum was given, did equally well with those to whom it had been given. There appeared to be no definite and regular reactionary improvement, such as one should expect after a specific serum. All varieties, as supplied by Colonel Gordon, were tried. The more the existence of mild and abortive types of the disease is recognised the less will be the tendency necessarily to attribute beneficial results to the serum administered.

#### *Bacteriological Diagnosis.*

(c) *Many cases fail to receive a true diagnosis owing to the frequent failure of modern bacteriological technique.* In all the diagnosed cases (150) at X Garrison in 1916 a Gram-negative intracellular diplococcus was seen in the spinal fluid. In more than half of the cases it was grown in culture and agglutinated. Twenty-one cultures were submitted to Colonel Gordon at the Central Laboratory and he agglutinated 18 of these to his types, 3 others being contaminated. The following table gives the numbers of examinations made of spinal fluids throughout the epidemic at X Garrison and also the results:—

—	No. examined.	No. negative.	Per-centage negative.	—	No. examined.	No. negative.	Per-centage negative.
Week ending—				Week ending—			
March 11 ...	19	1	5	April 15 ...	26	9	34
„ 18 ...	25	2	8	„ 22 ...	13	9	69
„ 25 ...	11	1	9	„ 29 ...	23	12	52
April 1 ...	23	3	13	May 6 ...	8	4	50
„ 8 ...	24	7	29	Total ...	172	48	27%

The special study of atypical cases began early in April. It caused an increase in the negative results. During the last three weeks the percentage of negative returns increased greatly. During this last period a positive bacteriological result was only recorded when the organism was grown on culture. This was in accordance with instructions received from Colonel Gordon. There was no doubt that during this period many of these cases, returned as negative, were actually suffering from cerebro-spinal fever. The symptoms in many cases were open to no doubt, and one intracellular organism, identical with the meningococcus, was seen in the spinal fluid.

Captain Samut, in his report of 1916, had shown the increasing difficulty of demonstrating meningococci in the fluid from early and milder cases where the fluid is clear. The difficulty of obtaining a culture increases under like conditions. Sometimes, however, an abundant growth was obtained on culture of fluids in which the meningococcus could not be seen, and, on the other hand, a purulent fluid, in which meningococci could be seen in abundance, sometimes failed to give a growth.

At X Garrison at this time we were making a study of irregular types at the earliest possible moment after the onset of symptoms, and a large number of negative results were to be expected, and were it not for Captain Samut's painstaking researches it is believed our negative results would have been still higher.

It was sometimes found that patients suffering from meningitic symptoms gave an apparently sterile fluid on first puncture, yet on repeating the operation at a later date meningococci were abundantly present. Captain Scott in 1917 showed the writer a patient at X Garrison; clinically, the symptoms left the diagnosis in no doubt, yet it was not until the fourth puncture that meningococci could be found.

It would appear, therefore, that neither the failure to find organisms on direct examination, nor a negative cultural result, can be relied upon to exclude a diagnosis of cerebro-spinal fever. In the second family mentioned above a child whose blood and spinal fluid were both (apparently) sterile was afterwards diagnosed by finding the meningococcus in a synovial fluid.

Other writers have noticed the weak points of bacteriology in the diagnosis of this disease. Worster-Drought<sup>2</sup> said that "bacteriological results are apt to be misleading, if relied upon, as clinical symptoms are often well advanced before organisms can be either seen or grown." Gaskell found fluids sterile at one puncture and positive at the next, and 6 out of 25 clinically definite cases failed to show the meningococcus. In the R.N. Reports of 1915-16, it is stated that "at Shotley, there were 11 cases bacteriologically diagnosed, and there were 11 others in which lumbar puncture was performed with negative results. Some of the latter suffered from severe and persistent headache at the time, and in some, paralysis and mental derangement followed."

#### *II. The Prime Importance of Unrecognised Cases in the Spread of the Infection.*

It would appear that indefinite cases, which often pass unrecognised, are in reality the more numerous, and that comparatively few progress to the stage where the symptoms are unmistakable. The indefinite cases are usually found associated with others of the usually accepted types, and between the two extremes are intermediates of all stages of severity.

The apparently sporadic occurrence of the majority of cases of this disease has often been commented upon. Two or more adult patients are not often found, associated in infection, and possessing all the classical signs of cerebro-spinal fever. Yet in our experience at X and other stations, it has nearly always been possible to trace a connexion between such definite cases, and others who have suffered from a form of pyrexia of uncertain origin. This connexion is chiefly noticed where the conditions as to housing and ventilation are unsatisfactory. In children, however, it is far from uncommon to find one or more unequivocal cases amongst the other children exposed to the infection. This frequency of multiple infection in children may be explained by the intense susceptibility of those of tender age to reflex irritation of the central nervous system, so that even a slight disturbance more often provokes in them characteristic cerebral phenomena, and cerebro-spinal fever is generally recognised as a disease of childhood. The meningeal scream and convulsion of a child cannot but suggest meningitis, whereas the headache, backache, fever, and vomiting of an adult may frequently fail to do so.

The diagnosis of cerebro-spinal fever is therefore probably more frequently and accurately made in children, and this largely serves to explain the greater infectivity and the higher incidence of the disease as reported amongst them. In adults, on the other hand, the variability of the symptoms frequently tends to the non-recognition of many cases and to the consequent failure in tracing the infective connexion between different forms of the same disease.

#### *Variation in Resulting Infection.*

The effects produced by a given dose of meningococci depends on the susceptibility of the patient rather than on the virulence of the organism, because the infection received from an acutely severe case may result only in a mild and indefinite illness in the person next infected, and, on the other hand, a patient with a mild illness may reproduce a most virulent infection in another.

This mutation in the type of resulting infection is well illustrated in the two families already mentioned. In the first family the first child, whose symptoms were so mild that the disease was unrecognised, infected its eldest sister with fulminating cerebro-spinal fever. In the second family an acutely fatal disease resulted in three other children being variously attacked, one of whom was proved to be suffering from cerebro-spinal fever, although it had no marked meningitic symptoms, and the cerebro-spinal fluid was apparently sterile and uninvolved.

Though as a rule the onset of cerebro-spinal fever is sudden and definite, yet a considerable number of patients develop the disease insidiously. A close study was made of the

<sup>2</sup> Brit. Med. Jour., Nov. 18th, 1916.

interval between onset of symptoms and admission to hospital in 45 consecutive cases at X Garrison; it was found to average 50 hours. During this time they were treated as extern patients, and must have constituted a virulent focus of infection to their comrades in barracks. The fact that unrecognised and irregular types tend to be more insidious in their onset than the definite and fulminating forms causes the former to be a much greater danger than the latter in the spread of the disease.

As already stated, the possibility of irregular and unrecognised forms of cerebro-spinal fever was first suspected by the writer by the undoubted association between proved cases and certain other febrile conditions, which differed in the intensity rather than in the essential characters of the symptoms. Very many individual instances could be given of a similar nature to the three families mentioned above. The evidence in these cases, though circumstantial, yet was so often repeated, and of such a conclusive nature when investigated on the spot, that it perforce led to no other conclusion than that such variation of symptoms as existed were due to the susceptibility of the patient and not to any difference in the common infecting organism.

Again, the simultaneous outbreaks of vague febrile diseases occurring in constant connexion with epidemics of cerebro-spinal fever, and the exactly proportionate incidence of both illnesses in various units and garrisons, as pointed out above, cannot be due to the chance incidence of two separate outbreaks in all of the units concerned, and the inference is again more than justified that a single organism is responsible for both types of illnesses.

The occurrence of these indefinite febrile outbreaks has been constantly noted by all observers. Dr. W. H. Hamer, medical officer of health of the London County Council, has given most interesting evidence of the association between them and epidemics of cerebro-spinal fever. In the Royal Naval Reports for 1914-16 the frequency with which unrecognised or aborted cases occurred amongst contacts of actual cases is discussed. Dr. Bruce Low, commenting on an outbreak at Northampton several years ago, wrote as follows:—

"There were also in this instance, coincidently with the 30 unequivocal cases, several others of an anomalous sort, mostly amongst persons who had been in contact with one or other of the patients who had been seriously ill; these cases resembled influenza and all recovered. .... This is the more interesting from the fact that the serious cases and those with only influenza-like symptoms occurred side by side."

### III. Carriers.

*There is no evidence at X Garrison to show that carriers convey active infection. The statistics as to carriers are conflicting and inconclusive. Their isolation is impracticable and unjustifiable.*

At X Garrison 520 carriers were isolated for varying periods up to four months. 187 carriers had been detected amongst the contacts of cases and 333 from the general body of troops examined when leaving the station on active service or otherwise. Captains Armstrong and Napier had isolated most of these on the result of morphological appearances because time did not permit of serological tests of the greater number of swabs. At the close of the epidemic Captain W. J. Tulloch was deputed by Colonel Gordon to complete the examination of the 324 men then remaining in isolation. This officer found that 103 of these were not infected with an agglutinable organism, consequently, as Colonel Gordon mentions, "persons harbouring such non-agglutinable meningococci should not be regarded as, or treated as, carriers of the organism."

Of the original 520 persons in isolation there were therefore at least 150 men who were not carriers at all. If carriers are capable of carrying infection it seems extra-

ordinary that each of these soldiers escaped infection when surrounded by 400 virulent carriers. They lived together for weeks and months in the hospital enclosure under somewhat unsatisfactory conditions.

Neither did any of the 400 active carriers develop the disease, nor any of the 504 known carriers isolated by the Central Cerebro-spinal Fever Laboratory as a result of the swabbing at X Dépôt in the following year. Colonel Gordon says, "Only occasionally does the meningococcus succeed in passing the barrier of the mucous membrane of the naso-pharynx and penetrating to the meninges." Surely it ought to have succeeded in some of these 1000 men.

It is well known that carriers practically never develop the disease. So much so that it has been suggested that they acquire an immunity. This is negated at X Garrison, because one known carrier contracted the disease whilst employed as a nurse in the cerebro-spinal wards. He lived apart, and evidently got infected from his patients. Another ex-carrier got the disease three weeks after his discharge from the isolation camp, after three negative swabs. Of course, immunity does not explain why none of the 150 false carriers failed to become infected.

### The Carrier Hypothesis.

At X Garrison 14,000 men were examined to find the carriers as above. About 200 per day were tested. These numbers constitute a record for an epidemic, and they are

FIG. 2.

sufficiently large to give a fair index of the daily carrier-rate throughout the course of the epidemic. As seen from the chart (Fig. 2), the carrier-rate at the period of maximum incidence was low, but as the cases ceased to occur the percentage rose to a high figure (33 per cent.). These figures show that a low carrier index may coincide with a high case incidence, and vice versa, and might be taken to indicate that cases produce carriers, but not carriers cases.

The principal argument in favour of the carrier hypothesis has been the frequent discovery of a carrier amongst the contacts after the diagnosis of a case. The above-mentioned two families are the two instances of "evidence" of infection of cases by carriers as brought forward by Captain Flack. In the first family the father had been definitely ill on arrival home, and his children took ill two and three days after his arrival, and in the other family the father had been 10 days at home before his four children took ill, which would seem to indicate that the latter was in no way concerned with the infection of his children. Both of the fathers were found to be carriers after the illness. In the third family mentioned by the writer the father apparently infected his child with cerebro-spinal fever and wife with "influenza," but in his case he was not a carrier.

Carriers are found in all communities in larger or smaller numbers. In order to establish a case in favour of the carrier having caused the case, it is necessary to prove that the carrier, found as a contact, is actively pathogenic and different from the numerous other carriers universally present, or, that the proportion of carriers found amongst non-contacts is comparatively small compared with the numbers found amongst actual contacts of the patients. No one has, however, attempted to show a difference between pathogenic and non-pathogenic carriers. Neither have any statistics been produced to show a difference in the percentage of carriers among contacts and non-contact carrier groups.

*Some Statistics in regard to Carriers.*

At X Dépôt, which has been the test station for the officers of the Central Cerebro-spinal Fever Laboratory, it was shown that no more carriers are to be expected amongst contacts than amongst those persons in no way connected with the patients—there being 34 per cent. in each case at this station. At X Garrison our own experience was the same, there being the same number of carriers amongst the population generally as there were amongst those persons in close contact with the patient.

Whilst working at the Central Laboratory in 1917 Captain Tulloch kindly allowed the writer to examine his series of results of examination of type in the naso-pharynx of carriers found in connexion with definite cases of cerebro-spinal fever. He agreed that there was no undue prevalence of the type as found on spinal puncture and that found in the naso-pharynx of the carriers. Such a prevalence would be expected if a relationship existed as regards infection between case and carrier.

At X Garrison there were no carriers found in connexion with 45 of the 150 cases in this epidemic, 250 persons having been examined as contacts of these cases. They were well chosen, being chiefly those occupying the same tent, billet, or barrack room as the patient. This is rather remarkable, as the carrier-rate generally, as shown above, was high.

Three soldiers at X Garrison were negative in their naso-pharynx within 24 hours of the onset of the acute symptoms of cerebro-spinal fever; two others were negative 48 hours and two 72 hours before the onset (and two more were likewise negative within 72 hours of being taken ill). These men happened to be swabbed as contacts immediately after the diagnosis of a previous case.

Captains Armstrong and Napier examined, at the writer's request, the throats of 41 cerebro-spinal fever patients on admission to hospital. In 19 only was the meningococcus shown to be present. Captain Glover repeated the same test in the following year, also at the writer's request, in 4 proved cases we visited together, and in only one of these was the meningococcus found in the naso-pharynx. The swabs were taken and the cultures examined with especial care.

*Route of Infection.*

Many patients consequently who develop cerebro-spinal fever are apparently not infected by the meningococcus in their naso-pharynx either at the onset of the symptoms or within the period immediately preceding the onset. It would seem, therefore, that such patients have not received, nor are they likely to convey, infection via the naso-pharynx.

Colonel Gordon, with whom the writer has discussed the above findings, makes no comment on this work of officers from his own laboratory when he says that "the meningococcus is invariably to be found in the naso-pharyngeal secretion at the onset of the disease. . . . Only occasionally does the meningococcus succeed in passing the barrier of the mucous membrane of the naso-pharynx and penetrating to the meninges."

The opinions of many other observers are directly contradictory to these views. Surgeon-General Rolleston, in his account of Cerebro-spinal Fever in the Navy,<sup>3</sup> says that "During the acute stage of cerebro-spinal fever swabs from the naso-pharynx are often negative. Out of 33 cases, bacteriologically proved, meningococci were found in 7, or 21 per cent. only." These results are in agreement with von Lingsheim's figures of 635 cases of cerebro-spinal fever with 146, or 22 per cent. of positive cultivations, from the naso-pharynx, and with those of Gaskell and Foster, who likewise found that only 25 per cent. of their cases were infected in their naso-pharynx. Netter's results show that only 60 per cent. are infected. In the Special Advisory Committee's report it is mentioned that "the meningococcus has been much less commonly found in the naso-pharynx of actual sufferers than might have been expected."

Recent work has thrown considerable doubt on the long-established belief that meningococci pass direct through the nasal mucous to the meninges. In many cases, certainly, the blood is infected prior to the cerebro-spinal fluid, which apparently often remains free of infection throughout, as in the case of the child already mentioned. It is more in accordance with modern ideas that the transmission should be via the blood.

*Types of Organism.*

The chief argument in support of the carrier theory given by Colonel Gordon is that he invariably finds the naso-pharynx infected by the same type of organism as is found in the spinal fluid. This evidence is already disproved, as above, by his own staff and others, who more often than not failed to find the meningococcus in the naso-pharynx. He believes that four types of meningococci exist, which are specifically distinct "and not transient and unstable variants of a single micro-organism." Again, other workers are unable to agree with him in this. Walker Hall and others find that the types are subject to mutation on culture. Bassett-Smith found that of 107 carriers who had more than one positive examination, more than half of them showed a variation of the Gordon type on subsequent swabbings. Eastwood, Griffiths, and Scott believe that the distinction between types is arbitrary and depends on the chance selection of strains.

Colonel Gordon has recently<sup>4</sup> replied to the contradictory observations (by other workers) with regard to his classification of meningococci. He explains their results as follows:—

"The research is of a distinctly arduous character—demanding a very high degree of dexterity that can only be acquired by continuous and persevering effort—even minute errors may mar or upset the result. In our experience at the Central Laboratory it requires at least six weeks' hard work before even a trained bacteriologist, with considerable serological experience, can sufficiently master the technique to obtain consistently satisfactory results. Similarly, when he goes on a holiday, even for a week, it requires at least another week's work before the necessary unconscious manipulative dexterity returns. After that degree of dexterity is reached irregular results are far less frequent than before."

It would seem as if the technique is so far above the ordinary well-trained bacteriologist that it loses much of its practical value.

Two, three, or four of these specifically distinct organisms are present in most epidemics. This seems very incredible from an epidemiological point of view. It is comparable to finding para. A and B and typhosus bacilli, irregularly, in the investigation of a definitely localised epidemic of typhoid fever. It would mean that each outburst of cerebro-spinal fever is due to two, three, or four distinct organisms being simultaneously let loose to produce infection. This seems so unlikely that it causes us again to hesitate before accepting the view that four specifically distinct organisms are concerned in epidemics of cerebro-spinal fever.

*The Isolation of Carriers.*

The prophylaxis for 1918, as approved by Colonel Gordon, is given.<sup>5</sup> The sixth and last recommendation is "that large sample swabbings (100 men) be taken weekly as a guide to the current carrier-rate." It is understood that case-contacts were to be swabbed as before, and that carriers from both sources were isolated. Such a proposal appears unsound and unjustifiable if it has involved the loss of man-power by isolation of carriers, as in former years. It can only be hoped to discover a small proportion of carriers by this procedure, for as, ordinarily, samples represent but a small fraction of the whole population so therefore the carriers found in sample groups represent the same fraction of the total number of persons carrying.

The practical effect of such a scheme was illustrated at X Garrison in 1916. At the close of the epidemic there the writer reported as follows:—

"It was decided to stop the further swabbing of drafts and to discharge the carriers then in isolation, further cases having ceased to occur. It seemed no longer logical to detain in strict isolation 400 men when recent swabbing results indicated that there were at least 5000 carriers living at large amongst the troops."

The discharge of the carriers was, however, countermanded by Colonel Reece and the further history is given by Captain Tulloch in the Medical Research Committee's Report, Series 3, but 60 of them had actually been discharged without ill-effects.

Again, at X Dépôt, which had been under the continual observation of the officers of the Central Laboratory for two years, it was known that during the epidemic half of the population (5500) were carrying, yet at the same time about 200 healthy men were detained as carriers in hospital.

<sup>3</sup> THE LANCET, Jan. 13th, 1917.<sup>4</sup> R.A.M.C. Journal, January, 1918.<sup>5</sup> Ibid., p. 35.

At X Garrison and at X Dépôt the samples were taken on a record scale, 17,500 men having been swabbed and over a thousand carriers isolated, yet at no one time did the carriers amount to one-twelfth part of the total number of carriers available. The population in both was largely a floating one.

There is no reason why case carriers should be isolated any more than carriers from sample. At the above dépôt the carrier-rate amongst the two groups was exactly the same (34 per cent.), and, as previously stated, no one has ever suggested that the carrier found in connexion with a case differs in any way as regards infection.

The possibility of failure in detecting a carrier would appear to be at least 20 per cent., judging by the writer's examination of the results of repeated swabbings of chronic carriers, where intermittent negative results were followed by positive findings. Fildes and Wallis' report:—

"If two consecutive negative swabs (the Navy require six) are taken as the index of cure, no less than 36 per cent. of men will, in fact, not be cured and will be returned to the community in the same condition as they were before they were isolated." And they concluded as follows: "One-third of the men recover spontaneously. None of the methods of treatment tested has any conspicuous merit, nor has any one obvious advantage over another."

It seems most irrational, therefore, to elaborate an extensive system of control which fails in detecting infection in nearly a quarter of the cases examined and which permits more than a third of the infected persons to be discharged uncured, and which detains healthy men for a treatment which possesses no obvious merit. Moreover, the isolation of case and sample carriers can never hope to deal with more than one-twelfth of the total numbers of carriers in a community.

#### *Methods of Treatment of Carriers.*

The impracticability of former methods of preventive control by isolation of carriers has now evidently become apparent (vide Colonels Reece and Gordon). It is recently admitted that "when the carrier-rate is high this procedure loses its value," and consequently a new procedure has been adopted—"inhaling-room treatment, which offers valuable help at any point where isolation breaks down." This treatment is still in an experimental stage, and up to the commencement of 1918 no tangible evidence was produced of its value. It would seem to be a tactical measure, which serves to focus the attention on a healthy carrier, and covers the retirement from the former position which had become untenable.

Various types of inhalers have been already tried—the Lingner-Gordon, Falmouth, and Levick. The last type, which was issued in large numbers in 1917, appears to have been replaced by the Hine pattern in 1918, the advantage of which is that "the atmosphere is not vitiated by the fumes of the burning spirit, as with the Levick spray." Many disinfectants have likewise been tried. The results from chloramine appeared to have been considered the best:—

"Though still somewhat few in number, they are more than encouraging, chloramine having given better results than any other antiseptic yet tried in this way." Yet the next year at the X Dépôt it was mentioned that "as the treatment was new it was considered advisable in this instance to begin with zinc sulphate, because it is less irritating than chloramine." Yet the previous year Colonel Gordon reported that "the results with zinc salts were disappointing, but they served to emphasise the success of those obtained with chloramine. Only one known carrier could be subjected to the zinc spray—this carrier required no less than 70 inhalations before he could be discharged."

The above extracts from published reports of Colonel Gordon and the officers of the Central Cerebro-spinal Fever Laboratory are given to show on what little evidence these officers have submitted to the public this new form of treatment.

Fildes and Wallis included chloramine in their tests as to the value of local antiseptic in the treatment of carriers, and their opinion has been given above of the value of this and other forms of nasal disinfection.

The writer has not had much definite personal knowledge of the value of the treatment. The published results are few and without statistical value. It has been claimed that it is equally effective in reducing the incidence of measles, sore-throats, &c. The writer noted, however, that at

D Garrison the battalion which had been severely infected by cerebro-spinal fever and which underwent elaborate spraying afterwards suffered abnormally from such complaints as compared with other units who were not being sprayed, there being 72 cases of measles and an excessive amount of bronchial catarrh in the sprayed battalion during April, 1917. The spraying arrangements were under the personal supervision of Major Hine and other officers from the Central Laboratory. The local opinion was unfavourable to the spray.

#### *IV. Prophylaxis.*

*The infection of cerebro-spinal fever is not to be feared under good conditions of housing and ventilation. The early isolation of mild and severe cases and the provision of free ventilation compulsorily, and with sufficient warmth during the time of seasonal prevalence, constitutes the most effective means of prevention.*

The proposed prophylaxis of the disease in 1918 is given by Captain Glover.<sup>7</sup> The measures indicate a considerable change from the policy of former years, and as they are stated to have been submitted to the advice and criticism of Colonel Gordon it may be taken that they embody the general aspect of control of the disease in the immediate future. They are as follows:—

(i.) Spacing out of the beds with a minimum interval—reduction of numbers from the mobilisation to the peace scale of accommodation; the provision of increased warmth and extra fuel; the overcrowding of Y.M.C.A. and other institutes, and medical inspection rooms to be limited.

(ii.) Special ventilation to be arranged, the windows to be fixed open, and new ventilating apertures to be provided.

(iii.) Inoculation to be postponed until the second month of service.

(iv.-vi.) The remaining measures deal with the spraying of all troops for six days each month, and the sample swabbing of 100 men weekly to afford a guide to the carrier index. The expediency of the two latter proposals has already been fully discussed.

For the first time it is noted that primary importance is attached to ventilation and overcrowding. Formerly such factors were not regarded as of importance by the officers of the Central Laboratory, judging by the conditions described as prevailing at X Dépôt at the commencement of the epidemic, a station which was under the personal observation of these officers for over a year before, as a test in preventive measures, and, in fact, it was stated that "it cannot be said that there were many cases to be attributed to overcrowding."

#### *Overcrowding and Defective Ventilation.*

The influence of overcrowding and defective ventilation as factors in the spread of cerebro-spinal fever was very definitely laid down in the writer's report of the epidemic at X Garrison in 1916. The following extracts are given:—

"The infection of cerebro-spinal fever is not to be feared under good conditions as to housing and ventilation. Accommodation was supplied on war scale, nominally at 40 square feet per man, but it was found that this space was not always available. The weather was abnormally cold and wet, and natural ventilation was reduced to a minimum, all doors and windows being closed. Orders were found insufficient to prevent this. The shape of the barrack rooms did not permit of a sufficient interspace between the beds. Unless sufficient fresh air is provided compulsorily and scientifically—i.e., out of reach of the soldier and with regulated draught—it will not be of practical benefit, as it will be put out of action. It is at night that ventilation is essential. Extra blankets should be provided to lessen the discomfort of cold air. Kinemas and crowded institutes are to blame for many cases of cerebro-spinal fever, the Y.M.C.A. huts being the worst offenders. I have inspected such places at night, and from these visits I am convinced that they are a most potent cause of spread of the infection."

On April 2nd, 1916, the minimum floor space was increased to 60 square feet. The doors and top sashes of all windows were fixed in an open position or else removed. The barrack rooms were inspected nightly by company and medical officers to ensure that ventilation was maintained. It is believed that the absence of further cases amongst the troops remaining in barracks was due more to the compulsory fresh air than to the smaller proportionate increase of floor space which it had been possible to obtain. (The troops had again been temporarily on the reduced scale owing to unavoidable reasons).

The lesson would appear to be that ventilation should be compulsorily given, and on a large scale. If absolutely necessary, moderate overcrowding on mobilisation scale may be permitted if the fullest use is made of fresh air. The incidence of cerebro-spinal fever is dependent on the thermometer. When the weather is cold ventilation is decreased automatically. Sunshine has no effect in preventing infection, unless accompanied by heat, as infection takes place in barracks and other places after sundown. Rainfall has no effect, neither has the barometer."

The proposal to defer inoculations until the second month of service will not, it is believed, reduce the well-known increased incidence of the disease amongst recruits. It is based on the known fact that about 40 per cent. of patients have been inoculated within a week of the onset of their illness, but, under present conditions, it is usual for such a proportion of men to have received a dose of inoculation or vaccination during each week of their early service.

*Practical Measures Advocated in Original Report.*

In conclusion, the following paragraphs may be repeated as concluding the original report:—

"The occurrence of a definite case is heralded as a rule by indefinite cases, and such should be an indication for all concerned to take such steps as the ætiology of the disease suggests. It is not sufficient to issue orders regarding open windows and overcrowding. The rooms should be visited by company and medical officers to ensure that instructions are carried out. Windows and doors will need to be screwed permanently open or removed. Dark blinds over the windows will need to be removed at 'Lights out,' but blankets and fires should be provided to lessen the discomfort of cold air. The ventilation and crowding of institutes requires most careful watching and personal inspection at the busy period of the evening.

On the occurrence of a case in the barrack room extra precautions will be taken on the lines mentioned, and a watch kept for febrile illnesses amongst the remainder. Any men suffering from severe headache, backache, and vomiting should be early admitted to hospital under observation. The contacts of a case do not require to be isolated or swabbed. They can continue their outdoor work as usual and sleep in the infected room for a week at least. During this quarantine period free ventilation should be insisted upon. All febrile cases amongst the troops generally should be at once detained in hospital.

These remarks are written in the hope that they may cause others to consider the possibility and importance of atypical and unrecognised forms of this disease, from the point of view of diagnosis, treatment, prognosis, and prevention. The early isolation of mild and severe cases, rather than of carriers, together with the provision of free ventilation, is suggested as the basis of preventive measures.

We claim to have established a case in favour of the prevalence of mild and atypical cases of cerebro-spinal fever. The influence of such cases in determining the spread of this disease is shown by the proportionate incidence of definite and indefinite illnesses, in units and garrisons, as well as by the many individual instances of mutual infection between them both. If the existence of these cases be admitted, it seems necessary in these circumstances to believe that mild and severe forms are equally potent and important factors as regards the spread of infection if it is considered that mild breeds severe and the severe mild, the resultant disease being dependent only on the susceptibility of the patient receiving the infection. Such considerations necessarily involve a review of the previous methods of the prevention of cerebro-spinal fever." (1916 Report.)

*Postscript.*

The following extract from the Medical Supplement (July, 1918), compiled by the Medical Research Committee, has just reached the writer—after writing the above. It is given here as it completely confirms the main contentions in the article.

"The significance of meningococcal carriers in the spread of the disease, as reflected in German medical opinion, is summarised by Galambos, who says that though sporadic cases of cerebro-spinal fever were observed in the various theatres of war there were never any epidemic outbreaks. G. B. Gruber regards the search for meningococcal carriers and their isolation and disinfection as unnecessary, and states that as regards importance they are on a par with pneumococcal carriers. Feser is of the same opinion and has never seen a proved case of infection by contact. The search for carriers is considered by Klinger and Fourmann to be both unnecessary and impracticable. Meningococci were never isolated from the naso-pharynx of 18 cases of cerebro-spinal fever under Galambos's observation, and no carriers were found among the contacts of the patients; he is convinced that isolation of healthy carriers has no influence in preventing the incidence of the disease."

## TRAUMATIC RUPTURE OF THE INTESTINE.

By W. H. BATTLE, F.R.C.S. ENG.,  
SURGEON TO ST. THOMAS'S HOSPITAL, ETC.

DURING the past five years many accounts of the modern treatment of gunshot wounds of the abdomen have been published, and the results have fully confirmed the opinion held by most surgeons as to the importance of interference as early as possible, given fairly satisfactory surroundings. This conviction led those in charge of the medical arrangements with the British armies to make special provision for dealing with this class of case as soon as possible, thus enabling a large proportion to be treated successfully. These results have never been equalled in previous wars, and will probably never be surpassed.

*Traumatic Rupture of Intestine without External Lesion.*

In civil life the same need of prompt action arises in cases where reason exists to suspect a perforation or laceration of some part of the gastro-intestinal tract, whether there be a lesion of the overlying structures or not. If no lesion of the skin is evident (and in many cases of abdominal injury where the intestine has been ruptured it has not been possible to find any) it requires firmness to induce the patient to submit to operation before peritonitis has made the need for operation obvious to the patient's friends. Waiting imperils success and often ensures failure. It is not always remembered by those in charge that septic peritonitis will be commencing within six hours and quickly spreads when it has begun.

Traumatic rupture of the intestine without an external wound is one of the catastrophes of civil life against which it is not possible to guard. There are many ways of causation, but practically no remedy without operation, and early operation. Peritonitis of the worst type inevitably supervenes. Although a few cases have been saved by surgical interference when peritonitis has been advanced, the loss of every hour makes the odds against recovery more formidable. It is far better to operate in a doubtful case and find contusion or slight laceration of some internal organ than to allow a valuable life to be sacrificed through a mistaken trust in the possibilities of treatment mis-called conservative.

In some of the more serious cases the shock is so intense that although the surroundings may be favourable the surgeon is compelled to wait. Still, there is a great responsibility on him to take the measures best calculated to enable the essential operation to be done as soon as possible.

*Record of Case.*

The following is the record of a case of rupture of the jejunum with laceration of the mesentery and intraperitoneal hæmorrhage.

A boy, aged 15, was admitted to St. Thomas's Hospital on August 29th, 1916. At mid-day he was riding a tradesman's bicycle, when a van ran into it and knocked him off. He was unable to give a clear account of the accident. He was suffering from shock and complained of severe abdominal pain. Normal urine was withdrawn by catheter. He was put to bed and warm blankets and hot-water bottles applied. At 2 P.M. the shock was still very severe and he complained much of the severity of the abdominal pain. He was white, with blanched lips, a subnormal temperature, and pulse of 118. He was lying on his left side with limbs and trunk flexed. Respiration almost entirely thoracic, the abdomen not moving. The muscles of the abdominal wall were rigid, but not board-like, and he was generally tender in this region. Pain was referred to a point about 3 inches above the umbilicus under the left rectus muscle. No evident injury to the skin. Dullness on percussion extended from the left flank to the level of the umbilicus when he was examined in the position assumed as the most comfortable. During the afternoon, whilst we were waiting for him to revive somewhat from his collapsed state, he vomited and became restless; there was also increasing dullness in the abdomen and continuing pain.

*Operation.*—At 4 P.M. a general anæsthetic was administered and the abdomen opened by a vertical incision about 6 inches long to the left of the middle line. The rectus sheath was opened and the muscle drawn outwards. The peritoneum had a bluish colour from underlying blood, which escaped in considerable quantity when the incision was extended. There was so much more than is usual in these cases of traumatic rupture of intestine that the spleen and liver were at once examined; they were without trace of injury. When the

omentum had been displaced to the left a large transverse rupture of the jejunum presented. This was situated about 6 inches from the duodeno-jejunal junction and extended over five-sixths of the circumference of the gut, there being only a strip of the mucous membrane on the mesenteric aspect, which appeared normal. This was wrapped in gauze to prevent further escape of faeculent fluid until the source of the bleeding had been discovered. This proved to be a tear in the mesentery behind the lacerated gut; in this a vessel of some considerable size had been torn. Other small lacerations were found near it, whilst an irregular laceration of the parietal peritoneum to the right of the spine, about the level of the umbilicus, required one or two sutures. The tear in the jejunum was also bleeding and the edges were bruised, so after the application of clamps excision of this part was performed, for a distance of 3 inches above and 3 inches below the rupture, and an end-to-end union made. The mesenteric lacerations were sutured. No. 1 silk was used for the anastomosis, an inner continuous uniting all the coats, and an outer Lembert, also continuous, covering in the line of union. The abdomen was cleansed, but owing to the evident contamination from intestinal contents a tube was left in. The small intestine was nowhere inflamed, but near the tear were some brownish patches, which did not come away on sponging. During the operation saline was infused intravenously. The pulse rose to 160, falling later to 120.

On the following day the pulse was improving though still rapid, and the boy was better. On the 31st he complained of pain and tenderness in the abdomen, and vomited. The lungs appeared clogged with mucus, there being moist sounds all over. Respiration 48, pulse 130. Dr. G. Hoffmann, who saw him for me, advised adrenalin and a mixture containing potassium iodide. Atropine and morphia injections were required to relieve his pain. There was little discharge from the tube, which was removed on the fifth day.

On Sept. 2nd the bowels acted freely, but his chest complication did not recover until Sept. 5th, when the pulse had come down to 96 and the temperature returned to normal. He left the hospital for a convalescent home on Sept. 27th.

A few months later he had a somewhat severe attack of pain in the abdomen which alarmed him, but this was traced to over-indulgence in raw chestnuts, and soon passed off after appropriate treatment.

#### Diagnosis.

After an injury which may have caused a rupture of some part of the intestinal tract there may be a group of symptoms making diagnosis certain and enabling decision at once, but there is no one symptom always present. Certain cases do not show leading symptoms until some hours have passed, and then a rapid change takes place.

It is not necessary here to repeat a list of symptoms which are very well illustrated by the above case, and which are found, luckily, in a majority. There is an agreement about this group and the indications to be generally expected, which I have dealt with elsewhere.<sup>1</sup> I should like to draw attention to two points: (1) the occasional rise of temperature; (2) the state of the abdomen.

A rise of temperature to 103° F. and over may be found when other symptoms are not well marked, and should be regarded as indicating a definite lesion of the wall of the gut, and one which requires repair. There may not be a lesion which has opened the lumen of the bowel; it may only involve the external layers, but it may become complete secondarily; therefore it requires repair. Incipient inflammation of the lungs secondary to an accompanying traumatism of the chest must be excluded by examination.

The usual state of the abdomen is one of immobility due to rigidity of the muscles, and, although there may be great tenderness, there is seldom dullness in the flanks. There may be dullness directly over the lesion, but this is usually quite restricted in amount and due to collapsed gut with slight hæmorrhage and some escape of contents. If there is abnormal dullness in the flanks, it may be the result of hæmorrhage from laceration of the mesentery, spleen, or liver. But the instances in which the state of the abdomen is recorded with reference to this point are not so numerous as we could desire.

The presence of free gas in the peritoneum, even in small quantity, appears to be somewhat rare if we consider the number of cases in which it was found when the peritoneum was opened. Mention is made of it in 5 only of the series of 132 brought together by Berry and Giuseppi; of these, 4 were ruptures of the jejunum, the opening in one instance being the size of a threepenny-bit; in 1 it was present on the twelfth day after a secondary perforation an inch below

the sutured one. Others appear in records to which we have access at the present time, but in only one successful case, an operation 20 hours after the injury, was there distension with loss of liver dullness. Loss of liver dullness after subcutaneous rupture of the intestines usually indicates a late stage, and is of bad prognosis, being caused by overlapping of the hepatic border by distended and paralysed intestine. Berry and Giuseppi say:—

"In several cases in which operation was not undertaken until absence of liver dullness had been noted, not one of these recovered."

In traumatic rupture there is collapse of the gut near the laceration, and the contents of the intestinal canal are therefore less likely to escape than they are when a pathological perforation is present. Free gas, and in large quantity, is common after perforation of an anterior gastric ulcer, but if the ulcer is small there may be none. It is seldom capable of demonstration after duodenal or jejunal perforations, although some may be found when the peritoneum is opened. Emphysema of the abdominal wall without accompanying fracture of ribs indicates a lesion of the duodenum or large bowel.

#### Operation.

The special points to be remembered in the operation for suspected rupture of the intestine are the following:—

1. The incision should be a long one, extending well above the umbilicus, as this gives best access to the root of the mesentery, and permits of most rapid examination of the abdominal contents. If the rectus muscle is temporarily displaced outwards and the posterior layer of the sheath divided well to the left of the mid-line (and it is best to place the whole incision to the left) there will be no danger of subsequent hernia.

2. Blood or fluid which has accumulated should be washed away with moist sponges and a search made for the source of the bleeding. When hæmorrhage has been arrested the damaged section of gut is looked for; this will usually be found in a line between the point struck and the spine. Before this is treated search should be made for a second point of rupture, for there is more than one in some 20 per cent. Apparently lesions of the upper jejunum have proved difficult to find, for those in this position have been overlooked in several instances, only to be revealed post mortem. Ruptures of the duodenum give the most anxiety, because there is usually excessive shock causing delay in the operation, great difficulty in localising the lesion, and when it is found more manipulation is needed to remedy the damage, the time thus required further imperiling the success of the operation.

3. Treatment of the lesion found will depend upon the extent of damage to bowel wall and to mesentery. A large laceration may be clean edged and as safely secured with a double suture of silk or other material as those of smaller size, but if the damage to the wall of the bowel is severe or there is another opening close to the one which was first discovered it may be necessary to resect and perform an anastomosis. The sutures will thus be placed in healthy tissue and valuable time saved. It is quite impossible to lay down hard-and-fast lines as to whether the laceration should be sutured, resected, &c., or not. Most recoveries, as would be expected, were after rapid suture. The use of Murphy's button did not prove very satisfactory, partly because it was used by operators who were hurried by the critical state of their case. Temporary artificial anus in the small gut is only to be tried when there is no time for anything beyond. Still, it must be recollected that John Croft's first case lived one month, only dying then (after secondary resection) from exhaustion.

4. Closure of the abdominal incision may be effected in the majority without drainage of the peritoneum; if drainage is required a suprapubic "stab-incision" will suffice, the tube being passed deeply into the pelvis. The course followed should depend on the presence or absence of peritonitis and the possibility of cleansing the infected peritoneum. When in doubt drain and place the patient in the Fowler position. When drainage is established much benefit may be derived from the use of continuous administration of saline by rectum during several hours.

#### Statistical Data.

In compiling statistics of a series of cases such as these it is somewhat difficult to avoid overlapping, and therefore a

<sup>1</sup> THE LANCET, 1916, i., 587.

want of accuracy, unless great care is exercised. The available records extend for useful purposes from the first case operated on by John Croft in 1888 to the end of last year, 1918. In the oration on Internal Abdominal Injuries given before the Medical Society of London<sup>2</sup> (1910), a list was given adding to that by Berry and Giuseppi.<sup>3</sup> Another useful addition was made by Raymond Johnson<sup>4</sup> in 1914, whilst St. Thomas's Hospital Reports and the medical journals have supplied others, completing, I believe, the list of those available from Great Britain. This gives a total of 221, comprising 200 males and 21 females.

Of these, 43 are derived from the records of St. Thomas's Hospital, of which number 33 were submitted to operation and 11 recovered. In 10 no operation was performed, chiefly because the condition was too bad from shock, general peritonitis, or the complication of some severe injury. One refused operation. Of these, life was prolonged in four for six days, eight days, four weeks, and four weeks respectively. Of the general series, 124 operations were performed with 48 recoveries and 76 deaths.

The hospital cases (St. Thomas's) are all given and include every case admitted, whether moribund or not, whereas the other statistics are from many sources and put the results in too favourable a light. Many fatal cases have not been published.

#### *Cause and Site of Rupture.*

The cause of the rupture is shown in the accompanying table, which also gives the part of the bowel injured. I have not included two cases of traumatic rupture produced by gunshot of the wall of the abdomen without wound of the peritoneum, although from a surgical point of view they are unusually interesting.<sup>5</sup> No case is included from any of the hospitals since those published in the list given by Raymond Johnson, unless published separately in the Journals. This statement does not include St. Thomas's Hospital.

—	Duo- denum.	Jejunum.	Ileum.	Small gut.	Large gut.	Totals

Position and cause not given in 6. Of the 21 females 15 were run over in the street.

#### *Summary of Other Cases.*

Other cases which have been under my care are the following:—

Male, aged 24. Jejunum, ruptured in two places: (1) Resection of 13 inches, and lateral anastomosis; (2) end-to-end with plates. Six hours after kick from horse. Lived 6 days; peritonitis from giving way of suture in end-to-end anastomosis.

Male, aged 27. Ileum; rupture  $\frac{3}{4}$  inch; sutured; drainage. Fifteen hours after run over drunk; 10 days later abdominal wound gave; re-sutured. Albuminuria and pulmonary symptoms. Lived 26 days.

Male, aged 50. Ileum; 3 ruptures; sutured; drainage. Immediate operation when admitted on fourth day with peritonitis; died a few hours later.

Female, aged 33. Splenic flexure; openings into peritoneum sutured. Retroperitoneal opening sutured; drainage of this. Operation 10 hours after run over. Recovered.

Male, aged 5. Ileum. Small opening sutured; 3 hours after knocked down by horse. Broncho-pneumonia. Recovered.

Male, aged 15. Jejunum. Resection and end-to-end anastomosis for transverse rupture. Laceration of mesentery. Acute bronchitis. Recovery. Case described above.

Two other instances admitted to my wards. 1. Rupture of duodenum. Operation abandoned because of rapid collapse of patient, did not permit of adequate exploration. 2. Operation by resident assistant surgeon after secondary giving way of damaged part was unsuccessful, and peritonitis proved fatal.

#### A NOTE ON

### THE VALUE OF SOLID PARAFFIN WAX IN FACIAL SURGERY.

By SPENCER MORT, M.D., CH.B. GLASG.,  
F.R.C.S., F.R.S. EDIN.,

LIEUTENANT-COLONEL, R.A.M.C., COMMANDING SPECIAL MILITARY  
SURGICAL HOSPITAL, EDMONTON, LONDON; LATE ASSISTANT  
REGIUS PROFESSOR OF SURGERY, UNIVERSITY OF GLASGOW.

FOR years melted wax has been advocated in filling in defective parts and raising the skin and superficial tissues of depressed areas, especially in injuries and defects of the nose. Since the war, I have operated on a good many cases of facial deformities, particularly in the earlier months before the Special Face Hospital was established at Sidcup. I regard all facial defects as worthy of the highest art of surgery. Patience, with dexterity, will repay all the trouble expended, as a good result will brighten a patient's life.

Having experimented with all kinds of plastic and solid material for the reconstruction of face defects, I suggest solid wax, pure hard paraffin, of melting point  $110^{\circ}$ – $115^{\circ}$  F., for introduction into the tissues as a permanent splint. Melted paraffin has many disadvantages, and personally I find it almost hopeless. The syringe usually gives great trouble, and the wax is put in hot and scalding or else it solidifies in the needle. Press hard on the plunger and a quantity may suddenly be thrown under the skin, solidifying in a lump at the wrong place, and not to be extracted without scarring. Further, melted wax will adapt itself to the skin tissues probably in the wrong place, instead of which we should have skin tissue moulded and adapted to the shape of the wax. Cases, too, have been known of sudden blindness following melted wax injections.

For these reasons, principally, I am using solid, cold wax, cut to shape, and introduced through a small prick. All the above disadvantages are eliminated.

#### *Technique.*

The following is the technique in the case of saddle-nose: (1) Sterilise the wax efficiently by melting in a pot. If surgical wax is not obtainable a Price's candle melted is a good substitute. (2) Make a quarter-inch prick near the depressed part with a tenotome. (3) Elevate around the incision to the required extent with a small elevator. (4) Have the wax poured out to depth of about half an inch in a porringer and solidified in a basin of cold sterile water. (5) Remove the wax *en bloc* from the small dish with an elevator. (6) Break to size (it will not cut properly) and afterwards trim the small splint to shape with a knife. The little shaped splints are about  $\frac{1}{4} \times \frac{1}{4} \times \frac{1}{2}$  inch. Several may be deposited in the one subcutaneous tunnel. (7) Push the wax into its place through the incision, stitch the wound with a fine catgut stitch, and apply a collodion gauze dressing. It will be found best in practice to do these operations in stages, and just too little at a time. More can be done later. Small pieces of wax will lie in the tissues undisturbed and unabsorbed; larger bits might work out through the wound. A useful practical hint is to avoid smearing the little incision with wax, as this tends to delay primary union of the skin edges. Rather drop the piece right into the undermined skin, then push it home. At the conclusion of the operation a vigorous massage of the nose while the patient is still under the general anæsthetic will be found to give an artistic finish to the part. The operation is splendidly simple in actual detail.

In conclusion, I have found melted wax of no service for hide-bound scars to be elevated. These must be raised by undermining with a raspatory through a small incision and kept in position by a solid bar of wax. The cases I have recently operated on have, indeed, been gratifying in their success, and so I venture to propose this method for certain special surgical cases. A depressed skin deformity of an unsightly nature on any part of the body may be similarly treated.

Edmonton.

At Ilfracombe it has been decided to provide an X ray apparatus, with a suitable building, in connexion with the Tyrrell Cottage Hospital, as a war memorial. The cost of the scheme is about £1000.

# THE EXPECTATION OF LIFE IN PULMONARY TUBERCULOSIS,

WITH SPECIAL REFERENCE TO PENSIONS ASSESSMENT.

BY RALPH M. F. PICKEN, M.B., CH.B., B.Sc. GLASG.,  
D.P.H. CAMB.,

ASSISTANT MEDICAL OFFICER, HEALTH DEPARTMENT, GLASGOW.

IN assessing the disability of discharged men for pension purposes various factors require to be considered. In practice the probable percentage defect of working capacity over a certain period is the main concern of a Medical Board; but other forms of disability have bearing on pension assessment, and an important one is the extent to which disease or injury, attributable to or aggravated by Army service, is likely to shorten life.

In many cases of gunshot wound, for instance, although working capacity is impaired, it can safely be assumed that the probable length of life will not materially differ from that of the average individual of the same age. Where, however, the disability arises from certain types of injury, and especially from disease, it includes curtailment of life as well as immediate reduction of working capacity, as, for instance, in cases of malaria, nephritis, chronic dysentery, heart disease, pulmonary tuberculosis, &c. In some diseases, indeed, it is possible that this factor is more important than the other.

For most of these diseases, however, insufficient information is available to enable the probable duration of life to be estimated, but it should be possible to come to some estimate in the case of pulmonary tuberculosis, which has now been a notifiable disease for a number of years, and concerning which fairly reliable statistics are in existence. Parenthetically, it may be remarked that if such information can be utilised for national purposes, it is an argument for some form of notification of diseases, whether they come under the category of infectious or not.

The figures quoted in this article have been taken from a detailed analysis of the after-history of cases of pulmonary tuberculosis compiled for departmental purposes.

## *Expectation of Life in Notified Male Cases of Pulmonary Tuberculosis.*

Table I. shows the percentage of male survivors distributed in age-groups at May 31st, 1917, of patients who were notified as suffering from pulmonary tuberculosis during the calendar years 1910 (when notification was introduced) to 1916, and concerning whom information was available at the date of inquiry. The average time between the notification of each group and the date of inquiry varies, therefore, from rather less than seven years to less than one year.

TABLE I.

Pulmonary tuberculosis: 7169 male patients notified 1910-1916; percentage surviving at May 31st, 1917.

Year notified.	Age-groups.						
	15-20	20-25	25-35	35-45	45-55	55-65	65+
1910... ..	12.3	13.7	14.1	19.4	26.0	21.0	9.8
1911... ..	15.6	17.6	20.6	18.8	16.9	4.8	Nil.
1912... ..	25.5	27.1	22.4	27.0	16.8	12.4	6.7
1913... ..	30.0	30.1	30.5	26.3	15.7	10.6	4.0
1914... ..	31.5	38.2	35.6	35.0	31.8	27.5	5.4
1915... ..	38.5	47.9	43.2	37.9	34.6	21.4	14.3
1916... ..	60.9	78.1	60.9	53.4	42.4	47.1	26.5

Patients under 15 years of age are not included, partly because there is a high proportion of wrong diagnoses at these ages and partly because such statistics would not be applicable to ex-service men. It will be observed that, especially at the higher ages, the percentage survival of cases notified in 1910 is actually higher than among those notified in more recent years, indicating that at the commencement of notification there was a greater tendency to notify elderly patients who were probably suffering from some other disease, such as chronic bronchitis. It will also be noted

that the percentage survival of cases at the age-period 20-25 is consistently somewhat higher than in other age-groups. Apparently the disease kills less rapidly at these ages.

The general trend of the figures suggests that if the information covered a longer period of time the percentage survivals would follow the course of a geometric progression. If the survivals for the age-groups 15-45 (comprising 5033 cases) are combined, eliminating the less accurate readings at higher ages, and a curve is drawn approximately to fit the percentages, it is found that, especially for survivals after two or three years, the curve follows approximately that of a geometrical progression and a factor can be easily calculated which will carry it on until it meets the base line. From a combination of the actual and hypothetical figures, rearranged to give survivals at 6 months, 1½ years, 2½ years, and so on from the date of inquiry, an expectation of life has been calculated and found to be 3.4 years. A separate estimate for the age-group 20-25 gives an expectation of 3.5 years, the difference, therefore, being so slight as to be negligible, in view of the fairly large error carried by any such rough method.

## *"Arrested" or "Improved" Cases.*

The above calculations apply to all male notified cases at the ages mentioned. The average age of these patients at date of notification closely approximates to 30 years. They include cases at all stages of disease and probably many in whom the diagnosis is wrong.

It is important to obtain some estimate of the expectation of life of patients in an early and hopeful stage of the disease and in whom also the diagnosis has been established with reasonable accuracy. For this purpose the after-history of a group of patients of the sanatorium<sup>1</sup> grade when they first came under notice, was followed. Only those who were discharged from sanatorium with disease "arrested" or "improved"<sup>2</sup> were included, and all those concerning whom the diagnosis was considered wrong or very doubtful, as well as those about whom information was not available at the date of inquiry, were discarded. The absence of tubercle bacilli in the sputum was not regarded as an essential factor in diagnosis, as it is a well-established fact that many true cases of pulmonary tuberculosis occur in whom tubercle bacilli are rarely or never found in the sputum. The patients were mostly insured persons coming from and returning to homes in Glasgow.

Table II. deals with a group of male patients admitted to sanatorium for the first time and discharged therefrom with disease "arrested" or "improved" between 1911 and May 31st, 1916, comprising 631 cases. It shows the percentage of survivals at May 31st, 1916, May 31st, 1917, and May 31st, 1918. Deterioration is obviously occurring rapidly.

TABLE II.

Pulmonary tuberculosis: 631 male cases discharged from sanatorium with disease "arrested" or "improved" before May 31st, 1916.

Date of inquiry.	Per cent. surviving.	Average time elapsed since discharged from sanatorium.
May 31st, 1916 ... ..	81.4	22 months.
May 31st, 1917 ... ..	66.8	34 "
May 31st, 1918 ... ..	55.0	46 "

The information can be analysed in more detail, however, and may be stated as in Table III.

TABLE III.

Pulmonary tuberculosis: 631 male cases discharged from sanatorium with disease "arrested" or "improved" before May 31st, 1916.

Date of enquiry.	Per cent. surviving after lapse of average periods from discharge in months.					
	6	18	30	42	54	66
May 31st, 1916 ... ..	97.2	79.4	73.4	72.5	—	—
May 31st, 1917 ... ..	—	82.6	66.7	58.2	53.3	—
May 31st, 1918 ... ..	—	—	67.7	58.9	45.8	44.0
Averages ... ..	97.2	81.0	69.6	61.9	48.3	44.0

<sup>1</sup> The term sanatorium, as used here, does not include tuberculosis hospitals for advanced or chronic cases.

<sup>2</sup> Roughly, 75 per cent. of discharged sanatorium males.

In this table the percentage of survivors is again shown separately at May 31st, 1916, May 31st, 1917, and May 31st, 1918, but the cases have been split up into groups discharged severally at intervals of, on the average, six months up to 5½ years. The results, where they exist for the same period in more than one group, are combined in the last line of the table, so as to reduce errors of chance. These percentages form the basis of a very crude life table and the expectation of life calculated as above is found to be 6.6 years. The average age is again 30 years.

#### *Expectation of Life compared with the Normal.*

The expectation of life calculated for so-called "arrested" cases alone is certainly greater, but the number of cases is so small (117 males) that it is impossible to place much reliance on any conclusion drawn from their study. The expectation of life calculated as before is, roughly, 14 years. This figure must be regarded as little more than a guess. It is probably too high, since the cases in whom arrest was obtained included a number where an element of doubt as to the diagnosis remained. Moreover, it must be admitted that the differentiation of mere improvement from arrest depends largely on the predilections of the medical officer estimating the result of treatment, so that patients discharged from one sanatorium as "arrested" would be discharged from another as "improved" and vice versa.

Now the expectation of life of a male, aged 30 years, in Glasgow was 29.68 years for the period 1881-1890,<sup>3</sup> and may be taken for practical purposes as 30 years for the period covered by this inquiry. The expectation of life of the "arrested" case of pulmonary tuberculosis is therefore less than half the normal, and of the "arrested" and "improved" ex-sanatorium cases taken together roughly a fifth of the normal.

In view of the fact that the average age of discharged tubercular soldiers is probably under 30 and the normal expectation of life, therefore, greater than 30 years, the probable curtailment of life itself would appear to be justification for assessing for pensions purposes all verified cases of tuberculosis with "arrested" disease at least at 50 per cent., and preferably at 60 per cent. In the opinion of the writer, fitness for work should not be stressed in fixing the minimum assessment.

#### *Graduated Assessment.*

The graduated assessment of disability in cases of pulmonary tuberculosis, according to the character and stage of the disease, presents difficulties which are of the same nature as those discussed at the commencement of this article.

Broadly speaking, a patient who is suffering from the more chronic form of the disease, who will not derive benefit from sanatorium treatment, and who is not urgently requiring a bed in a hospital, will benefit psychologically and will not materially suffer from a moderate amount of work of a suitable kind, although his prospect of life is brief. It would seem desirable to avoid creating an impression that the pursuit of employment on the part of an ex-service man will affect the assessment of his pension, and rather to aim at providing him with maintenance on a level entirely dependent upon the character and stage of the disease. Further, the local authorities responsible for the institutional treatment of tuberculosis admit many patients for preventive reasons and not mainly because of the patient's clinical condition. The tendency is to assess such men as totally disabled. The ex-service man who has a comfortable home and chooses to remain there and to do a certain amount of work suffers in comparison with the careless patient who, on account of his poor home surroundings, is admitted to an institution and is therefore assessed as a person requiring institutional treatment. Practically, the problem can best be solved by a liberal assessment in all unequivocal cases of tuberculosis of the lung, and the inquiry recorded above indicates the justification for such a policy even toward arrested cases.

#### *Difficulties in Estimating the Activity of the Disease.*

The presence of disease which is actively progressive, as indicated by bacteriological and X ray examination, physical signs, continued loss of weight, swinging temperature (actually observed or recorded by the medical officer of a Public Health Department or institution dealing with the

case), rapid and unstable pulse, &c., is sufficient ground for an assessment of 100 per cent.

The graduated assessment of men below 100 per cent. but above the minimum assessment permitted is bound to be associated with a large error, and the solution is probably to be found in diminishing the number of possible intervals. The writer's own experience is that the more familiar one is with this disease the more one will hesitate to make a prognosis, and assessment is, after all, a prognosis in accurate terms. The chronic fibroid type of disease may be associated with a considerable degree of unfitness for work and yet with comparatively prolonged life. On the other hand, the expectation of life of a patient with a small active lesion at one apex may be very much shorter.

In the writer's opinion the extent of lung tissue involved is of limited value for prognostic or assessment purposes, and forms of classification such as the Turban, Turban-Gerhardt, or that based on the number of lobes diseased, suffer in practice from the undue emphasis laid on the local condition as estimated by physical examination. Even where provision in the classification is made for taking account of the patient's general condition, the majority of observers are naturally influenced in their estimation of the general condition by their observation of the extent of lesion. A measure of the activity is what is wanted, and disease of low activity, but not arrested, would naturally fall into the intermediate grade.

#### *Proposed Method of Assessment.*

The method suggested is that cases of tuberculosis should be assessed in three grades: all those with actively progressive disease at 100 per cent., those in whom the disease is arrested at 60 per cent. or 50 per cent., and all those intermediate at 80 per cent. or 70 per cent. It requires to be emphasised that the presence of actively progressive disease is to be estimated not merely by the presence of rales or of tubercle bacilli in the sputum, but should be based more on the patient's general condition, especially as observed after the lapse of a period of time since his discharge from the Army; but in this matter the writer believes that guidance of the highest value may be obtained from examination by X rays. Whatever may be the limits of X ray examination—and these remain to be clearly defined—there is no doubt that actively progressive disease shows very clearly on a properly taken X ray negative as clouded or steamy shadowing.

The proportion of ex-service men falling to be assessed as "arrested" cases will probably be fairly high. It is a fact that many discharged soldiers who first showed evidence of tuberculosis in the Army, and in whom the records indicate that the diagnosis has been accurate (showing, for instance, the presence of tubercle bacilli in the sputum), are working regularly after a year or two and keeping in remarkably good health without ever having received sanatorium treatment. Many of these men who come before pensions boards show no present signs whatever of disease.

The facts suggest that ordinary treatment in a military hospital has been sufficient in their case to effect an arrest of the disease, and it is possible that they are evidence of the value of early diagnosis, arrived at as the result of the readiness of men on Army service to report sick before they have reached that degree of infirmity which generally leads a man in civil employment to give up work and seek treatment. It is possible, also, that many men with fairly strong natural immunity to tuberculosis have contracted the disease under abnormal war conditions of physical and mental stress associated with a manner of life conducive to infection, and that as soon as they have been removed from these conditions their natural recuperative powers have effected a cure. However this may be, the impression of the writer is that the percentage of "arrests" among discharged soldiers, and particularly among those who were not sent to sanatorium direct from the Army, is above the level of civilian experience.

The policy suggested implies, of course, that the greatest care will be taken to eliminate all cases of wrong diagnosis, and there is no doubt many such have occurred among men discharged from the Army as suffering from tuberculosis. The elimination of these will probably become simpler in the course of time, but in the meantime cases in which there is grave doubt whether the men ever suffered from tuberculosis might be dealt with entirely on their own merits and

<sup>3</sup> A New Life Table for Glasgow, by Dr. A. K. Chalmers.

irrespective of any definite grading adopted for established tuberculosis. All men in whom there is a record of tubercle bacilli in the sputum, even if unequivocal physical signs have never been detected, must, for practical purposes, be regarded as definite cases, although in some instances confusion of specimens submitted to a bacteriologist may have occurred.

#### Summary.

1. The expectation of life of males aged, on the average, 30 years, notified in Glasgow as suffering from pulmonary tuberculosis is about 3½ years.
2. The expectation of life of male cases at a sufficiently early stage of the disease to raise hope of recovery is about 6½ years.
3. The expectation of life of male sanatorium cases discharged with the disease "arrested" is estimated at somewhere about 14 years.
4. The normal expectation of life of all males in Glasgow at the age of 30 years may be taken as 30 years, but was probably higher for the period covered by this inquiry.
5. The above calculations, applied to the assessment of soldiers and sailors discharged with pulmonary tuberculosis, justify a minimum assessment of 50 or 60 per cent., and this should apply to men in whom the disease appears to be arrested for the time being.
6. All cases where the disease is actively progressive, as measured by general signs and symptoms, physical signs, bacteriological and X ray examination, should be assessed at 100 per cent. disability.
7. All others—i.e., cases of low activity such as those of the chronic fibroid type—should be placed in one grade at 70 or 80 per cent. disability.

## THE LYMPHOIDOCYTE AND ITS CLINICAL SIGNIFICANCE.

By A. KNYVEET GORDON, M.B., B.C. CANTAB.,

FORMERLY DEMONSTRATOR OF PATHOLOGY, ST. MARY'S HOSPITAL;  
AND LECTURER ON INFECTIOUS DISEASES IN THE UNIVERSITY  
OF MANCHESTER.

THE lymphoidocyte is now regarded as the original ancestor both of the red and white corpuscles of the circulating blood. Amongst the evidence for this view, weight may be attached to the fact that in the foetus up till about the sixth month it is the only blood cell found in the lymph nodes and bone-marrow. From this period onwards the intermediate forms leading to the fully developed erythrocytes and leucocytes begin to appear in a definite sequence. After birth the lymphoidocyte is never found in the peripheral circulation in health, but may be present in certain diseases. When we attempt, however, to determine its pathological distribution in the blood we are met with two initial difficulties.

*Nomenclature of the lymphoidocyte.*—The first is one of nomenclature. Such is the confusion in which the literature of hæmatology has become involved by the multiplication of terms that the lymphoidocyte is found to possess no fewer than 89 synonyms. In the case of some authors it is almost impossible to ascertain to what type of cell their communications refer.

*The panoptic stain.*—Secondly, it is essential that the panoptic stain shall be employed, otherwise the characteristic structure of the nucleus, by which the lymphoidocyte can easily be recognised, is not well brought out. With Jenner's or Wright's stain, for instance, a lymphoidocyte may easily be mistaken not only for the pathological leucoblast, but even for a normal large hyaline cell. The same difficulty occurs, though to a less extent, with Leishman's stain, which has also the disadvantage of occasionally giving rise to nuclear precipitates. It follows, therefore, that many of the deductions of Ehrlich and his school before the introduction of the panoptic stain must be received with caution.

After making such allowance as is possible for these difficulties, we find that the occurrence of the lymphoidocyte in the peripheral circulation, though recognised in the case of the leukaemias, particularly those of the lymphatic type, is not mentioned in other diseases. The tacit assumption is made that its presence is associated with a marked total lymphocytosis. I fail to find any reference in

the English text-books of pathology to its clinical prevalence, though Gruner gives a full account of its biology.

Recently, however, I have had the opportunity of examining blood films from a series of cases of subacute bacterial endocarditis of the Libman type under the care of Captain H. J. Starling, M.D., at the Sobraon Military Hospital. Working with the panoptic stain and full controls I have so far found it in 10 out of 11 cases in the following proportions:—

Case 1, 6 per cent.; 2, 10 per cent.; 3, 2 per cent.; 4, 6 per cent.; 5, 4 per cent.; 6, 7 per cent.; 7, 7.5 per cent.; 8, 7 per cent.; 9, 8 per cent.; 10, 5 per cent.

This type of endocarditis appears to be invariably fatal, and of these cases Nos. 3, 4, 5, 6, and 7 are already dead and 1 is moribund.

As I hope to publish the hæmatology of these cases in extenso later on, I do not give further details, my present object being simply to record the presence of lymphoidocytes. I may say, however, that in no case was a marked leucocytosis present, and that it is possible to exclude any type of pernicious anæmia or leukaemia. It is evident, therefore, that their occurrence is not limited to the essential blood diseases.

The question then arose whether the appearance in the peripheral blood of this, the most primitive, type of cell, might not be of wider distribution and significance, whether it might not possibly be a sign of grave illness from divers causes. I therefore examined films from certain other cases, with the following results:—

CASE 11 and 12.—Moribund from old age, there being no clinical or pathological sign of any other disease; lymphoidocytes present in both to the extent of 6 per cent. and 2 per cent. respectively. Both films showed a moderate total leucopenia with slight relative lymphocytosis. Neither patient incidentally had shown any sign of influenza or tuberculosis.

CASE 13.—Moribund from gangrene of both legs. Lymphoidocytes 2.5 per cent.

CASE 14.—Diabetes. Lymphoidocytes 2.5 per cent.

CASE 15.—Carcinoma of liver. Lymphoidocytes 4 per cent.

The lymphoidocyte is well recognised in hæmatological literature, and many excellent drawings of it are published in the *Folia Hæmatologica* and in Gruner's *Biology of the Blood Cells*. The cell varies in size, but is usually about that of a large hyaline; its nucleus rarely fills the cell and is usually oval or slightly notched. It stains more faintly than that of either a leucoblast or a large lymphocyte or hyaline, and is distinguished by containing from two to four definite nuclei. The protoplasm is scanty, basophilic, and never granular.

It would seem desirable that extended investigation should be made on the pathological distribution of the lymphoidocyte in order that its full significance in the peripheral blood may be determined. I publish this note, therefore, mainly with the object of drawing the attention of other workers to the point. I should add that the staining reactions were controlled by observations of normal blood and marrow films, which were repeated on the examination of each case. Typical lymphoidocytes were obtained for comparison from smears from foetal bone-marrow, and from two cases of myeloid and lymphoid leukaemia respectively.

So far films from the blood of 10 patients who were not suffering from any obviously fatal disease have been examined, but without finding any cells that even resembled the lymphoidocyte. These comprise: Influenza + pneumonia, 6; carbon monoxide poisoning (recovering), 1; aortic disease with fair compensation, 3.

ROYAL CORNWALL INFIRMARY, TRURO.—The governors of this charity have recently issued an appeal for £8000 in order to equip the institution with adequate modern sanitary accommodation and to make provision against fire, and also for other improvements. About £3000 have been raised for the scheme.

Dr. W. S. Thayer, of the Johns Hopkins Medical School, Baltimore, in a paper read before the Annual Congress of American Physicians and Surgeons, advocated the establishment of rehabilitation camps for civilians in time of peace, and said that the practicability of such a course had been shown by the war.

## Medical Societies.

### ROYAL SOCIETY OF MEDICINE.

#### SECTION OF PSYCHIATRY.

A MEETING of this section was held on July 11th, Dr. WILLIAM McDUGALL, the President, being in the chair. After announcing a letter of regret for his unavoidable absence from Dr. Bernard Hart, the President formally introduced Professor JUNG, who had come from so great a distance to read his paper on

#### *The Psychogenesis of Mental Disease.*

Professor Jung dealt with the history of the materialistic dogma in psychiatry, according to which a disease of the mind is a disease of the brain. Even to-day the alienists considered physical aetiology a matter of primary importance and psychogenesis as of very secondary interest. He quoted instances to show how this leads frequently to the neglect of important psychological factors. The origin of this misconception was to be found in our system of education. The neurologist receives a grounding in the natural sciences only, whereas a knowledge of psychology is essential to everyone who may be called on to treat mental disease. Then, too, under the present system only the most extreme cases of disease come before the alienist, who has thus no opportunity to study the early phases of mental disease. Apart from minor troubles such as phobias and obsessions, paranoia, hysteria, katatonia, and dementia præcox were the chief diseases in which no histological changes could be found in the brain. He admitted that in the last named changes did sometimes occur, but suggested that the toxins which produced degenerations might be formed in the course of the disease and be a secondary factor. Neurasthenia might be regarded as a mild form of dementia præcox, and in many cases the disease never reaches that aggravated form in which it is usually regarded as almost incurable. The worst cases of katatonia were, he thought, often due to the maladministration of overcrowded asylums, for cases of dementia præcox reacted to their environment in a way which would hardly be expected if one were dealing with an organic disease.

#### *Illustrative Cases.*

Professor Jung then related four cases of katatonia in support of his thesis that this disease is psychogenic in origin. In the first case the patient had had an unhappy love affair in a certain town, as a result of which he had quitted the locality, intending never to go back. On account of the fact that he had relatives in the district he did, however, eventually return, and on this occasion was seized with his first attack of katatonia. He recovered and remained perfectly well until he again revisited the scenes of his unhappy experience. Immediately upon returning for the second time he once more became katatonic. So that in six years the only occasions on which the patient was seized with this illness were those on which he was confronted with a powerful array of distressing memories. Another convincing narrative was told of a woman who, in the course of a family fracas, had been stigmatised by her husband as "mad," whereupon she had said, "Very well, if you call me mad you shall see what it is like to be mad," and had at once become so violent that she was removed to the mental clinic. There she had speedily regained a great measure of calm, but it was judged she should be kept under observation. She remained calm until she found that she was under restraint and could not immediately return to her home and then she again became very violent, so that it was at last found necessary to remove her to another part of the building. Here she recognised that she was among people who were definitely insane and cried out as before, "If you think me mad you shall see what it is like to be mad," and then fell into a condition of katatonia. A psychological predisposition was not enough in itself to cause a psychosis. In the absence of any mental conflict nothing abnormal might ever be remarked. But it was to be noted that such predisposition tended to produce conflicts and so to establish a vicious circle of disease. Only when the

patient finds that he cannot help himself, and that nobody is able to help him, does he become panic-stricken and so insane.

#### *Treatment of the Psychoses.*

Dealing with the treatment of the psychoses, Professor Jung said that it was perhaps too soon to give an opinion on the value of psychotherapy. Most of the cases which he had explored by analysis had been much too complicated for him to deal with them in the course of a single lecture. He had, however, met with one or two more simple cases, and one of these he related in considerable detail. The case in point was that of a girl, quiet and retiring by nature, who quite suddenly developed symptoms of mental disorder. She said that she spoke with God and with Jesus about war and peace and the sins of men. When seen by Professor Jung she was entirely unemotional, and exhibited no curiosity concerning her visitor or the nature of his visit. She admitted having had these conversations, but could not remember what had been said. When it was urged that she must have heard about matters of great importance and she should have made some notes of what she had learned, she showed a calendar whereon she had simply marked the date when these conversations had taken place. She displayed, in fact, no intelligent interest in the unusual event. She denied having had any religious troubles, but it was learned from the mother that on the evening preceding her hallucinations she had returned from a religious meeting somewhat excited, and had announced her complete conversion. Recognising that taciturnity is a mechanism of self-defence, Professor Jung had proceeded patiently to analyse this case, and in three sittings had traced the girl's history through a recent disappointment in love to a shock which she had received some years previously when at the age of 16 she had been severely punished for encouraging an aged idiot in certain obscene actions. It was at this time that she had become a quiet, rather shy girl, for previously she had exhibited a quite normal display of youthful spirits. This case was, in Professor Jung's opinion, clearly one of dementia præcox of psychogenic origin. The conflict in this instance had led to a complete severance of emotional rapport with the world of men. In a personality where there existed a tendency towards dissociation the same conflict would have caused not dementia præcox but hysteria. It was 10 years since the speaker had first claimed that destructive changes associated with dementia præcox are secondary manifestations of disease, though he did not deny that in certain cases they might be the primary cause of disorder.

#### *The Discussion.*

In the course of the subsequent discussion Dr. W. H. B. STODDART said that what criticism he had to offer came from one who was already converted to the psychogenic origin of mental disorders. Certain organic changes had, however, been observed in connexion with dementia præcox which could not be overlooked. General paralytics whose disease was unquestionably organic in origin did react very markedly to environment. He was not convinced that the cases which Professor Jung described were all of the kind which is generally known as dementia præcox in this country.

Dr. HENRY HEAD questioned whether such a disease as dementia præcox really existed. There were cases which began in the classical way and then became atypical—that is to say, they recovered. In any case, it was the mental condition which was of importance rather than the nomenclature. A disease might have a psychogenic origin in some cases and an organic origin in others. This was clearly the case in exophthalmic goitre, whose occasional psychogenic origin had been clearly demonstrated by the recent air-raids.

Dr. WILLIAM BROWN, speaking as a psychologist, expressed his great indebtedness to Professor Jung for his stimulating address. He emphasised the need for a prolonged investigation into the synthesis of mental disorders, quoting cases from his own experience, including one of disorientation which had ultimately yielded to analytical treatment only when a memory dating from the second year of life had been recalled. The question of the possible psychogenesis of epilepsy was also raised in the course of the discussion.

Professor JUNG, in replying, stated that in cases of major epilepsy psycho-therapeutic methods were of little success.

## Reviews and Notices of Books.

*The Pituitary.* A Study of the Morphology, Physiology, Pathology, and Surgical Treatment of the Pituitary, together with an Account of the Therapeutical Uses of the Extracts Made from this Organ. By W. BLAIR BELL. London: Baillière, Tindall, and Cox. 1919. Pp. 348. 30s.

DURING the last two decades much has been written about the pituitary gland, but still much remains to be done ere we can say much definitely about its functions and inter-relations. Dr. Blair Bell's own experimental work, begun in 1906, was primarily undertaken to elucidate the relationship of the pituitary to the female genital functions and to determine the physiological and therapeutical importance of extracts made from this organ. It soon became evident that such studies, to be profitable, must be based on a comprehensive investigation of the morphology, physiology, and pathology of this gland and its relations to metabolism in general and to the other endocrine glands and those that form hormone-poietic secretions. The outcome of such research is the splendidly illustrated volume under review.

The text is divided into four parts. The development, anatomy, histology, and comparative anatomy are set forth in Part I. (pp. 3-78). The scientific study of the pituitary began in 1838, when Rathke described the origin of the hypophysis from the primitive alimentary canal. We cannot follow the author into the many details of the comparative anatomy of the pituitary. Suffice it to note that in all vertebrates higher than the elasmobranchs there is a definite pars nervosa. Extracts made from this structure are active in all respects.

Part. II. (pp. 79-214) deals with the physiology of the gland and the methods for the investigation of its functions. Certain physiological states are associated with marked changes in the pars anterior. In pregnancy, both in animals and women, this part enlarges—there is an increase in the degree of eosinophilia or by chromophobia ("pregnancy cells")—the essential change during pregnancy is towards greater activity. Hibernation—e.g., in hedgehog and dormouse—also produces striking histological appearances, both in the epithelial elements of the partes anterior and intermedia—the secretory cells of this organ. In the pars intermedia vesicles with hyaline (? colloid) contents are almost always found, and may represent its normal secretion. Herring found "hyaline" bodies in the pars nervosa, derived, he thinks, from the pars intermedia which pass via the infundibulum into the third ventricle, and so into the cerebrospinal fluid. The author does not agree with this view. He thinks that the cells of the pars intermedia produce the pressor substance which he calls "infundibulin," and that this secretion and that of the posterior lobe are taken up by the blood stream. Therapeutically the most fruitful results seem to be obtained by intravenous injection of extracts of the organ as a whole or of its individual parts. Next the author deals with the effects of destruction and partial or total removal of the gland with the operative technique, describing a large number of his own experiments, and others also on separation and compression of the stalk. The author agrees with Paulesco and Cushing that total extirpation or removal of very large portions of the pars anterior is fatal, also that the removal of the pars posterior produces no symptoms. The author also finds that the genitalia not only do not atrophy, but continue to develop in the young female after removal of this portion of the pituitary. He differs from Cushing in finding that in none of the cases in which portions of the pars anterior were removed did dystrophia adiposogenitalis—with its lowered blood pressure and sugar tolerance—supervene. This syndrome, however, occurs after compression and separation of the infundibular stalk. The author reconciles these diverging views by assuming that this syndrome is primarily produced by insufficiency of the pars anterior, and that the only sure way to effect this is to interfere with the blood-supply. The inter-relations of pituitary activity with that of the thyroid and ovaries is fully dealt with.

Part III. (pp. 215-300) deals with disorders associated with the pituitary and their treatment. The author deals with hyperpituitarism and acromegaly, and describes the cases

which he has treated; also with hypopituitarism, which is usually not manifested until the child is growing up. The types before and after puberty are described and illustrated, including dystrophia adiposogenitalis. The surgical treatment of pituitary disease is fully dealt with and admirably illustrated.

Part IV. (pp. 301-329) deals with the therapeutic uses of pituitary extracts for which there are as many names as trade firms manufacturing them. The extracts used were made from the whole gland (pituitarin), pars anterior (hypophysin), pars posterior (infundibulin). The preparations are made as dried or liquid extracts. The former are given by the month, but infundibulin is given intramuscularly; this should be done with caution. The indications for their use are carefully noted and special attention is given to the use and pressor effects of infundibulin in shock, collapse, sepsis, serum-sickness, spasmodic asthma, chronic asthenia with low blood pressure, and in obstetrical cases—in which latter its uses and contra-indications are specially described. The author gives the results of his experience in the use of these extracts in other diseases, but they do not seem to be very encouraging. He says:

"The most notable effects and benefits of pituitary medication are obtained in those cases in which a rapid result is desirable. In such circumstances the extract used is that made from the pars posterior, and its action is exerted upon all the unstriated muscle-tissues of the body."

We congratulate Dr. Blair Bell on the success of his endeavour to lift a corner of the veil that still enshrouds the secrets of the pituitary body. Much work has still to be done before the potentialities are laid bare. Perhaps the author, who has already done so much original work to this end, will, in days to come, reveal to us something more of these fascinating mysteries.

*The Practical Medicine Series for 1918.* Vol. VII.: *Skin and Venereal Diseases.* Edited by OLIVER S. ORMSBY, M.D., and J. H. MITCHELL, M.D. Chicago: The Year Book Publishers. \$1.40. Price of the series of eight volumes, \$10 00.

THIS volume is one of a series of eight issued at monthly intervals, covering the entire field of medicine and surgery, each volume aiming at completeness on the subject treated for the year prior to publication. The aim is commendable and well realised in the present volume on Skin and Venereal Diseases. The amount of information it contains is large and it is presented in a stimulating manner. Due attention is given to the sociological, as well as to the purely clinical aspect of venereal disease. This is evidenced by the sections on Venereal Disease contracted in the Army, and the Teaching of Syphilis. Under the heading of Gonorrhœa there is an interesting note on phlebitis of the deep dorsal vein, a subject to which little attention has been devoted. An attractive feature is the criticism offered by the editor on the various statements enunciated in the text.

*The Ophthalmoscope: A Manual for Students.* By GUSTAVUS HARTRIDGE, F.R.C.S. Sixth edition. With 65 illustrations and four plates. London: J. and A. Churchill. Pp. 152. 6s. 6d.

THE first half of this book deals with the theory of ophthalmoscopic images and gives practical instruction in the use of the ophthalmoscope, covering largely the same ground as the author's book on Refraction. The second half deals with the normal fundus and a few of the abnormal conditions most usually found. Two coloured plates of varieties of the normal fundus will be found useful by the student, but the illustrations of abnormal conditions might well be improved.

*A Woman Doctor: Mary Murdoch of Hull.* By HOPE MALLESON, B.A. With a Preface by L. B. ALDRICH-BLAKE, M.S., M.D. Lond. With portrait illustrations. London: Sidgwick and Jackson, Ltd. 1919. Pp. 231. 4s. 6d.

THE life of a good physician is always worth recording for the sake of the medical generations to come. Many students—and especially the women students—will find inspiration in the story of Mary Murdoch's life. But we feel with Dr. Aldrich-Blake that this biography deserves a recognition beyond that of the medical profession. Her insight into human need and her rich possession in the fruits of human

happiness qualify this busy practitioner as an example to all who are striving for a higher conception of citizenship in the world. The biographer has wisely allowed Mary Murdoch to speak very largely for herself, and, indeed, no art could improve upon the transparent sincerity of her finely written letters. Collected in an appendix are to be found also some of her enthusiastic, yet well-balanced lectures and addresses, together with obituary notices published at the time of her death, and amongst these last the one which appeared in our columns on April 1st, 1916. We can well believe that the people of Hull still mourn and still miss their beloved doctor.

*A Handbook of Medical Jurisprudence and Toxicology.* By WILLIAM A. BREND, M.A. Camb., M.D., B.Sc. Lond., Lecturer on Forensic Medicine, Charing Cross Hospital. Third edition, revised. London: Charles Griffin and Co., Ltd. 1919. Pp. 317. 10s. 6d.

THE third edition of Dr. Brend's useful little book has been enlarged and brought up to date, the chapter on insanity and other abnormal mental conditions having been entirely rewritten. Both this chapter and the preceding one on the forms of insanity are as good as can be expected in so small a space. The section on insanity and criminal responsibility, dealing with the history and application of the M'Naughton ruling, is particularly clear and interesting. The book is essentially a convenient work of reference, and if read as such in connexion with law cases of current interest will prove of value alike to the general practitioner and to the medical student.

#### JOURNALS.

*The Journal of Physiology.* Edited by J. N. LANGLEY, D.Sc., F.R.S. Vol. LII., No. 6. Cambridge University Press. 1919. Pp. 391-474. 9s.—The Rate of Diffusion of Gases through Animal Tissues, with some Remarks on the Coefficient of Invasion, by August Krogh. It would seem that the supply of oxygen to cells has never been systematically investigated hitherto. The author describes fully his series of ingenious experiments. The diffusion constant for a gas through a substance is defined as the number of c.cm. (0°C. and 760 mm. Hg) penetrating through 0.001 (1  $\mu$ ) thickness and 1 sq. cm. surface per minute when the pressure difference is one atmosphere. The diffusion constant for oxygen through animal tissues increases with increasing temperature—about 1 per cent. per degree, taking the rate at 20° as unity. Diffusion of gases through animal tissues is much slower than through water or gelatin. The absolute diffusion constants for oxygen at 20° are: water, 0.34; gelatin, 0.28; muscle, 0.14; connective tissue, 0.115; chitin, 0.013; indiarubber, 0.077. The "invasion coefficient" for oxygen into water is many times higher than the "determinations" hitherto made would indicate.

The Number and Distribution of Capillaries in Muscle, with Calculations of the Oxygen Pressure-Head Necessary for Supplying the Tissue, by August Krogh. To utilise the foregoing data it was necessary to know further the rate at which oxygen is used up by the tissue in question, and the average distance which an oxygen molecule has to travel from a capillary into the tissue before entering into chemical combination. As the capillary arrangements in striped muscle are fairly regular, this tissue was chosen as the basis for study. To this end blood-vessels of certain muscles in different animals were injected. It was found that in striated muscles the capillaries are arranged with such regularity along the muscular fibres that each capillary can be taken to supply a definite cylinder of tissue, the average cross-section of which can be determined by counting the capillaries in a known area of the transverse section. The number of capillaries per sq. mm. of the transverse section of striated muscle appears to be a function of the intensity of the metabolism, being higher in small mammals than in larger forms. The necessary oxygen pressure-head deduced from the total number of capillaries is in all cases extremely low.

Influence of Saprophyte Bacteria on Oxidation in Higher Animals, by I. Kianizin. (Fifth series.) This is a short and interesting paper.<sup>1</sup> (1) The Respiratory Response to Anoxæmia; (2) The Effect of Shallow Breathing, by J. S. Haldane, J. C. Meakins, and J. G. Priestley. As to (1) it is known that ordinarily the respiration is regulated with the utmost delicacy in correspondence with the CO<sub>2</sub> tension of the blood passing through the respiratory centre, and that the centre actually responds to increased hydrogen-ion concentration. The apparatus used is described. In each case the subject of the experiment was sitting at rest while breathing from the apparatus. Records were taken with

each variation of the composition of the air breathed—e.g., 3.82 per cent.—4.29 per cent. CO<sub>2</sub>; other observations were made on altering the proportion of oxygen in the inspired air. It was found: 1. The respiratory response to anoxæmia is in three stages: (a) Increased depth of respiration and increased ventilation per minute owing to lowered CO<sub>2</sub> threshold; (b) periodic breathing unless the anoxæmia is considerable; (c) frequent and correspondingly shallow breathing. 2. Excess of CO<sub>2</sub> (increased hydrogen-ion concentration) causes a considerable and persistent increase in depth of respiration and relatively slight increase in frequency. This response is in marked contrast to the response to want of oxygen. 3. The maximum increase in lung ventilation is obtained when excess of CO<sub>2</sub> and anoxæmia are both present. As to (2), shallow breathing, there are two theories as to the harmonising of the regulation of respiration with the metabolism of the body—viz., (a) that it is a matter of reflex nervous control; and (b) that it is a chemical regulation. Investigations showed that there is a distinct connexion between the nervous control and the chemical control. The authors' investigations were carried out on men suffering chronically from the effects of gas poisoning and from a group of symptoms known as D.A.H., "soldier's heart," "irritable heart," "effort syndrome," attention being given to the regulation of the depth of respiration, more especially to the effects of shallow breathing. "Irritable heart" is characterised by breathlessness on exertion, rapid pulse, fainting attacks, giddiness, exhaustion, lassitude, headache, irritability, &c. These patients invariably show a remarkable type of breathing, which is rapid—20 to 60 or more per minute—and shallow—250 to 350 c.cm.—and on exertion the rate increases very abnormally, while the increase in depth is abnormally small. Their alveolar CO<sub>2</sub> is abnormally low. The patients are like a normal individual at high altitudes, where the diminished oxygen tension of the inspired air produces the same series of defects. All showed shallow rapid breathing. The concertina-like apparatus used for regulated limitation of the air inspired at each breath is described and by it records of rate and depth of the respirations were also obtained. It was found that shallow breathing caused unequal ventilation of the lungs, and this in turn produced anoxæmia and consequently periodic respiration and other symptoms. As to the effect of posture on the type and rate of respiration, the recumbent position is normally associated with slowing and deepening of the respiration, and if the deepening is prevented symptoms of anoxæmia are produced. Similar effects on the respiration were produced by abdominal and thoracic constriction—e.g., by use of corsets. These and other observations are regarded as affording an explanation of orthopnoea. In any condition such as bronchitis, asthma, and emphysema, in which the even distribution of the air in the lungs is hindered by local narrowing of the bronchi or local impairment of the lung elasticity, imperfect oxygenation of the mixed arterial blood must tend to be produced in the same way as in shallow breathing.

The Physiological Action of Extracts of the Electrical Organs of the Skate (*Raja clavata*) and Torpedo (*T. maritima*), by P. T. Herring. Extracts of the fresh organs made with Ringer's fluid were used, and their effects tested on the sartorius of the frog, on mammalian blood pressure, and volume of some organs. Electrical organs do not contain a hormone capable of influencing the contraction of cross-striated muscle. The extracts showed no special effects upon smooth muscle, cardiac muscle, blood pressure, or kidney secretion.

The Supply of Oxygen to the Tissues and the Regulation of the Capillary Circulation, by August Krogh. Direct observations by transmitted and direct illumination were made on the capillaries of the muscles of the tongue of deeply narcotised frogs, and also on other adjacent muscles, and on the muscles of urethane-guinea-pigs by reflected light. Capillaries are not mere passive tubes with the blood flowing through all of them at rates which are determined by the state of constriction or dilatation of the corresponding arterioles. Observations by reflected light on the resting muscles of frogs and guinea-pigs showed that most of the capillaries are in a state of contraction and closed to the passage of blood. By tetanic stimulation of the muscle or by gentle massage a large number of capillaries are opened up. They can be observed to contract again afterwards. In spontaneously contracting muscles a large number of capillaries are likewise opened. The average diameter of the open capillaries in resting muscle is much less than the average dimensions of the red corpuscles, which become greatly deformed during their passage. In working muscles the capillaries are somewhat wider. The oxygen pressure in resting muscles is, sometimes at least, very low, but in working muscles it approaches very near to that of the blood. The capillaries are not merely passively dilated by blood pressure, but constantly perform active variations in calibre. Clinical hyperæmia and anæmia are due mainly to

<sup>1</sup> A summary of previous work will be found in the Journal of Physiology, l., 1916.

changes in the calibre of capillaries and the number of open capillaries. The arterio-motor and capillario-motor systems seem to act in opposite directions.

This is a very interesting volume.

*Studium. Revista di Scienza Medica.* Junne, 1919. Pp. 40. Naples: Corso Umberto I. 154. Price 2 lire.—After three years of cessation owing to the war the publication of this monthly periodical has been resumed under the editorship of Dr. Tommaso Senise. We cordially welcome the re-issue with a passing tribute to the artistic design on the cover, with the inscription of "Scientia Lux Lucis," which recalls the style of Walter Crane. The new number contains an editorial review of the literature of the influenza epidemic, with special reference to articles by Trémolières and Rafinesque in the *Presse Médicale* of last February, by Professor J. Boni in *L' Ospedale Maggiore*, Dr. E. Ruggieri in the *Riforma Medica*, F. Schuffer in the *Rivista Critica di Clinica Medica*, and others.—Among other items one of the most important is the report by Professor Leonardo Bianchi to the After-war Commission, on the Biophylaxis and Prophylaxis of Neurosis and Psychosis. In this report he urges the necessity of modifying the Italian law of 1904 concerning insane people and asylums. This law enacted that reception into an asylum was to be limited to those who were a danger to themselves or to others; it was a measure of public safety, not a conception of treatment. The insane, the report insists, must be treated under all circumstances and not only when they are dangerous; the estimate of public safety emanates from a society saturated with bureaucracy from which the social scope of treatment is banished, to say nothing of that of educating the weak-minded.—Professor A. Cardarelli contributes a clinical lecture on Severe Intercoastal Neuralgia Symptomatic of Aneurysm and New Growths, and the editor has an illuminating paper on a New Method of Investigating the Functions of the Central Nervous System. This method consists in an experimental production of ischaemia in different areas of the brain by ligature of the arteries supplying those areas.—In the section devoted to Reviews, the more modern methods of treating tuberculosis are dealt with, notably that of Lo Monaco, by injections of saccharose.—There are also many extracts from current medical literature, notices of recent books, and general news. The *Studium* has now reached its ninth year of existence and we wish it every success in the future.

## Reports and Analytical Records

FROM

### THE LANCET LABORATORY.

UMBROSE.

(ALLEN AND HANBURY, LTD., 7, VERE-STREET, CAVENDISH-SQUARE, LONDON, W.1.)

THE "barium meal" used in radiological practice should, of course, be quite insoluble in water or acids, as the soluble barium salts are highly poisonous. This means that only the pure insoluble sulphate should be used for the purpose when barium is substituted for bismuth. There is no difficulty in obtaining quite pure barium sulphate free from soluble salts, as is shown to be the case with "umbrose." Shaken for several hours with dilute hydrochloric acid the filtered fluid, according to our examination, showed no trace of barium at all. This simple test, it seems to us, should always be carried out before using the preparation for radiological examination, as serious accidents have arisen either through the sulphate being contaminated with soluble barium salt or through the substitution of the carbonate or even sulphide. Such cases have been reported in our columns. Umbrose is mixed with a certain proportion of convenient pabulum—e.g., cocoa, arrowroot, dried milk—and leaves on ignition a pure white residue of barium sulphate, amounting, according to our analysis, to 74 per cent. A reliable shadow-meal is thus presented.

#### OMNOPON-ATRINAL "ROCHE."

(HOFFMANN LA ROCHE CHEMICAL WORKS, LTD. (SWITZERLAND), 7 AND 8, IDOL-LANE, LONDON, E.C. 3)

Containing the alkaloids of opium in their entirety and in a soluble form, omnopon has recently been combined with atrinal, a sulphuric ester of atropine (not the ordinary sulphate), as a preliminary and adjunct to narcosis by inhalation. Claims are made in favour of its advantages compared with the morphine and atropine sulphate combination, on the grounds that it is less toxic than atropine, its paralyzing action on the pneumogastric is less pronounced,

while it avoids the increased blood pressure following the use of ordinary atropine salts. It is also stated that it has no unfavourable effect on respiration. The combination is an interesting one and the claims made are of importance. Each ampoule contains 1.1 c.cm. of fluid, representing 0.02 g. omnopon and 0.001 g. atrinal.

#### CHELTINE FOODS (MILK AND MALTED AND STRICT DIABETIC).

(THE CHELTINE FOOD CO., CHELTINE WORKS, CHELTENHAM.)

We have received, amongst others, three specimens of the milk and malted foods made by the above company. Nos. 1 and 2 are designed for infant feeding, and No. 3 for invalids and patients with weak digestive function. Our analysis sets out their composition per cent. as follows:—

Milk and Malted Food.	No. 1.	No. 2.	No. 3.
Moisture ... ..	5.30	4.35	5.60
Ash ... ..	1.70	3.05	1.75
Fat ... ..	7.94	12.48	7.88
Protein ... ..	14.11	17.00	11.27
Sugars ... ..	14.85	22.30	12.00
Starch and dextrin ... ..	56.10	40.82	61.50
Total matters soluble in cold water ... ..	34.25	36.75	26.50

Food No. 1 is intended for infant feeding up to the fifth month, when it is replaced by food No. 2. In each case the food is directed to be prepared with diluted cow's milk. It will be noted that No. 2 is richer in all food materials, fat, protein, and sugar, than No. 1, from which it may be fairly inferred that more milk is used in this case. The conversion of starch by malt is not complete in both cases, but a greater conversion is shown in No. 2. Food No. 3 shows still more unconverted starch and dextrin, which, however, are readily dissolved or assimilated as the result of partial digestion with active malt. In addition, we have received two foods described respectively as (4) diabetic strict flour and (5) diabetic strict food. The main question, of course, in regard to these latter foods is the amount of sugar they are capable of yielding on hydrolysis. The results obtained in our experiments were as follows, in terms of reducing sugar after digestion with acid:—No. 4, 18.16 per cent. and No. 5, 16.00 per cent. They contain, therefore, about a fourth only of the quantity of sugar-yielding substances in ordinary flour, the carbohydrates being replaced largely by assimilable proteins.

#### ELIXIR YADIL.

(CLEMENT AND JOHNSON, 1A, SICILIAN AVENUE, LONDON, W.C. 1.)

Reference has been made in our columns<sup>1</sup> to the employment of yadil in influenza when its administration internally appeared to ward off the complications of that disease. Its active constituent is described as trimethenal-allyl carbide, a substance related to the essential oil of garlic. The ordinary preparation has a decided smell and taste resembling garlic, and for those patients who find objection to these characteristics an elixir is now prepared with suitable adjuncts and aromatics obscuring the allylic odour and taste. It is an amber-coloured fluid with sweet and aromatic flavour. Its antiseptic properties are claimed to be established in clinical practice.

#### SUPEROL.

(K. RAYMENT, 2, BROAD STREET-PLACE, BLONFIELD-STREET, LONDON, E.C. 2.)

Chinosol will be barely familiar under the name of "Superol," which is now being imported into this country from the Amsterdam Superphosphate Works by the above agent. A good deal of work has been done in regard to determining the germicidal value of chinosol, and while in some directions it compares unfavourably with other antiseptics, it possesses certain advantages of its own. Those whose experience with its application was satisfactory and who, through the war, were unable to get supplies, as it was exclusively produced in Germany, may be interested to know that its manufacture has been undertaken by the above company under the name of "Superol." It is identical, according to our examination, with chinosol, a combination of potassium sulphate with oxy-chinoline sulphate, the base being prepared by the oxidation of nitro-benzene and aniline.

<sup>1</sup> THE LANCET, March 15th, 1919, p. 440.

# THE LANCET.

LONDON: SATURDAY, JULY 19, 1919.

## The Federation of Medical and Allied Societies.

It will be remembered that at a conference between the Medical Parliamentary Committee and the representatives of other allied organisations held in May last certain resolutions were come to which were published in *THE LANCET* the following week.<sup>1</sup> The resolutions provided for the constitution of a permanent body with various duties towards the medical profession and towards the public, while the drafting of a financial scheme under which the work would be done was left to the existing committee, acting as a provisional body with the responsibility of making a report. The report, it was agreed, would be submitted to the representatives of the whole constituent bodies, and being approved, a new executive would come into being, when all the preliminary stages might be considered over. That was the project and so much has now been done. The Medical Parliamentary Committee has been reborn in what it is hoped will be a permanent shape; it has been renamed; its support for the future is under actual consideration, and it yet has to justify its existence by its works. Such is the outcome of the meeting held at the College of Ambulance last Friday, when the representatives of 47 medical and allied societies met the provisional Medical Parliamentary Committee, heard their report on the future constitution, and in the main adopted their scheme.

For reasons which seemed sufficient to the majority of those at the meeting, the Medical Parliamentary Committee now takes to itself the clumsier but more definite name of British Federation of Medical and Allied Societies, a brief discussion on this alteration of title answering an eternally old question by replying that "British" can be used as an adjective connoting all our Irish interests and all those of our Dominions over the seas. Those who look at the resolutions passed at the large meeting in May—and we hope that many will do so—will allow that for the rest the scheme, which has now been adopted, for carrying on the Federation under a change of name, and under some variance of scope owing to the multiplication of interests, has throughout the same general idea, and that this idea has prevailed since, at the meeting of the medical profession in Steinway Hall in October last year, the Medical Parliamentary Committee came into existence. At that first meeting Dr. CHRISTOPHER ADDISON moved a successful resolution to the effect that, "in the interests of national health it is essential that the considered views of the medical

profession should be voiced by representative medical men in the House of Commons." At the meeting last May the formation of a permanent medical committee was agreed upon by general resolution, having for its objective to supply expert information on health questions to medical Members of Parliament, to warn the bodies constituting the committee of impending legislation affecting such questions, to facilitate communication between any of those bodies where they were particularly interested, and, lastly, to assist in increasing medical representation in Parliament. The story is one of natural evolution. The stage has now been reached when, to carry out this programme, an executive has been elected and plans have been formulated for raising the necessary funds. Finance, as ever, lags behind, and while the meeting last week recognised the merits of the scheme proposed by the Medical Parliamentary Committee for financing the Federation in the future, discussion of the subject in detail is promised.

So much for what is, and while past experience of unified movements within our ranks makes optimistic prophecy risky, we see no reason why the new Federation should not have before it an immediately and widely successful career. Of course, if the Federation is not supported it will not be a Federation, and will effect nothing; equally, of course, those who decide to join the movement *only* when it is successful may in this case find themselves with no movement to join. But there is so much work ahead of the new Federation, and so real and wide a feeling that this work should be done, that we refuse to believe that any apathy, at this critical stage, will be allowed to nullify the strenuous efforts of the past six months.

## Hack v. Hack and Munden.

MR. M. M. MUNDEN is to be congratulated upon the verdict of the jury in the unsuccessful petition for divorce in which he was cited as co-respondent by Mr. H. S. HACK, the husband of one of his patients. The evidence in the case has been reported in unusual detail, and it was evident that the nauseous story told by the respondent and her maid, together with the letters produced by the latter, could yield no verdict other than that returned. This was made all the clearer when Mr. MUNDEN himself had been in the witness-box and when his evidence had been corroborated by his wife. The story which had to be met was one lacking in practically all those elements of probability which are usually present in the accounts of alleged conjugal infidelity laid before the divorce court. Mrs. HACK was the patient of Mr. MUNDEN from May, 1913, to the autumn of 1917, and she was, as he fully recognised, suffering from alcoholism and hysteria. He also attended her for more than one miscarriage. According to Mrs. HACK, he seduced her in the drawing-room in 1914, and from that time onwards committed adultery with her on various occasions under the cloak of professional attendances, for

<sup>1</sup> *THE LANCET*, May 10th, p. 808.

which, in fact, he charged as such. On one of the dates assigned to these acts Mrs. MUNDEN was waiting outside the house in the motor-car, in which she frequently accompanied her husband on his rounds. This in itself would be a story of unusual depravity and recklessness on the part of a medical man who had himself been recently married, whatever might be the physical or mental condition of the patient with whom he was intimate. When it is remembered, however, that Mr. MUNDEN was attending Mrs. HACK for alcoholism and hysteria, which was not in dispute, it will be seen at once that only the strongest proof of infatuation in no common degree on his part could render the allegations credible.

Folly and imprudence have limits even in those rendered blind by passion to the likelihood of such a woman betraying her lover, but in the case of Mr. MUNDEN and Mrs. HACK there was not a tittle of evidence of even the most casual friendship, or the most ordinary social intercourse. That he visited his patient as a medical man at intervals was common ground, and no witness on behalf of the petitioner attempted to prove anything more. Nor was there even anything to suggest that Mr. and Mrs. MUNDEN did not live together as a perfectly united married couple. In these circumstances it was only natural that Mrs. MUNDEN should be able to support her husband in his statement that he was only absent for the period necessary for a professional visit on a night when Mrs. HACK and her maid swore that he spent at least two hours in the bedroom of the former. In the same way the doctor's wife could state to a material extent what took place on another occasion when her husband and herself were interrupted at dinner by a visit from Mrs. HACK, who was taken by him into the surgery and afterwards got rid of. There was a singular absence of independent testimony from the whole case. Among the facts referred to, however, were the damning letters produced by the maidservant, to whose custody the respondent had entrusted them. They were written to Mrs. HACK by other men than the co-respondent, in terms that will have been noted by all who read them, and among them was no line of writing from Mr. MUNDEN. In short, the co-respondent, so far as the evidence went, had never sent to the respondent anything more incriminating than a prescription; and he will have the heartiest sympathy of all in the position in which he found himself placed.

Medical men know well that the case of HACK v. HACK and MUNDEN is not an isolated one, but an example of a class. It is a rare example of what may occur, but by no means without parallel. It is a danger which has to be faced by members of nearly all branches of the medical profession, that at any time a woman with whom they have been alone may make against them a charge of undue intimacy or of improper conduct of some kind without any ground whatever for doing so. There is no absolute safeguard against such charges, nor, of course, can we say that on all occasions when a medical man sees a female patient alone he ought to have a third person present. This would be a

counsel of perfection which in practice would not be possible of fulfilment. Precautionary steps may be taken in cases where symptoms displayed by the patient point to their being desirable, but always the principal safeguards for the doctor would appear to consist in confining the interview to the limit of time necessary for the matter in hand, and the keeping of strict records made with the least possible delay, which should contain all essential details of the patient's condition with the treatment recommended. The ethical rule which restrains a medical practitioner from discussing even with his wife the diseases or idiosyncrasies of his patients deprives him of a limited form of protection which he might otherwise have, this being especially so when there is no professional colleague with whom to discuss any salient points in the case or in the demeanour of a patient. Another way of avoiding risk is to refuse attendance, but it is a dangerous method for a young doctor to adopt—it does not improve his practice, and might lead to his being asked to formulate his reasons for his unusual conduct. A practitioner cannot be blamed for continuing his attendance in risky circumstances any more than a barrister can be blamed for continuing his advocacy on behalf of a client of whose probity he feels doubtful. The medical man will, however, exercise prudence and care in future attendances on such a patient, confident in his own integrity and honour, and not without some faith in the time-honoured maxim which ascribes ultimate victory to truth. To join one of the defence societies is absolutely necessary for the medical practitioner, and we congratulate the Medical Defence Union on securing the complete acquittal of their member from a ruinous charge.

## The Conditions of Asylum Medical Service.

THE Asylums Committee of the London County Council has just presented its report to the Council on a revised scale of remuneration and other improvements in the conditions of service of the assistant medical officers at the Council's mental hospitals. It may be recalled<sup>1</sup> that shortly before the war the discontent with their position felt by asylum officers throughout the country resulted in a movement for association to protect their interests and advance the status of asylum service. In May, 1914, a petition was presented by the assistant medical officers of the London asylums to the County Council asking for a betterment of their conditions of service and pay. A deputation then received explained the difficulties experienced by the Council in obtaining the staff for its mental hospitals by adducing three causes: for the unpopularity of the service. The specialty of mental diseases is alone in this country in not enjoying a teaching centre; opportunities for advancement in the lunacy service are practically non-existent; and, thirdly, outside the

<sup>1</sup> THE LANCET, 1914, i., 116.

strictly limited number of superintendentships the conditions of asylum service preclude any prospect of living a life of reasonable freedom and responsibility. The deputation suggested that facilities should be given for study-leave sufficient to enable medical officers to obtain a diploma in psychological medicine, and that officers should be seconded for the purpose of holding clinical posts at the Maudsley Hospital, of taking post-graduate courses elsewhere, or of carrying out research work. It was finally urged that permission to marry should not be withheld from any medical officer on the permanent staff after a reasonable length of service.

The war postponed consideration of these suggestions, and now that the matter comes up again for decision the Committee admits that the difficulties have increased rather than diminished, in view of the greater scarcity of qualified medical men and the growing attraction for the medical entrant of other branches of public service. In view of this the Committee proposes a drastic revision of the remuneration scale, the rate of pay for the first assistant being fixed at £700, equivalent to £875 with the present war bonus and percentage additions. His colleagues would similarly look to a salary running up to £755, £650, and £553 respectively in ascending order of seniority. This scale to count for the larger mental hospitals with 2000 or more patients. It is further proposed to remove the restriction upon the civil state of medical officers below the grade of second assistant, and to put them in this respect in the same position as the senior assistant who already finds suitable accommodation provided for him as a married man within the asylum precincts. Sympathetic consideration has been given to the points raised in regard to education, special medical qualifications, and leave, and a further vital change is submitted for the approval of the Council—namely, not to appoint any officer in future exclusively to a single institution, but to leave open the question of transfer from one mental hospital to another.

The time is, indeed, more than ripe for the suggested reforms. The life of the asylum medical officer has in the past tended neither to the efficiency of the service nor to the development of the medical officer's own powers and character. The disabilities in regard to marriage could hardly have been enforced by any authority possessed of human sympathy and social imagination. To the Ministry of Health, under the recent Act, it is lawful to transfer by Order in Council any powers and duties of the Secretary of State under the Lunacy Acts. The London County Council has already, without pressure from above, begun to set its house in order in regard to a proper mental medical service, but it remains to be seen whether the service can become such as it should be, in the interests of staff and patients, without being placed under the Minister who directs the other public health services of the country. The quasi-autonomy of the Board of Control is an anachronism.

## Annotations.

"Ne quid nimitis."

### THE OSLER PRESENTATION.

A DISTINGUISHED company, which included the President of the General Medical Council, the Director-General of the Army Medical Service, and the High Commissioner for Canada, assembled on Friday, July 11th, at the House of the Royal Society of Medicine, to do honour to Sir William Osler on the eve of his seventieth birthday. Sir Clifford Allbutt presented the two large octavo volumes of essays written by pupils, colleagues, and friends in all parts of the British Dominions and America, alluding feelingly to Sir William Osler's leadership in the relief of sickness and adversity, and to the fruitfulness of the marriage of science and letters exemplified in his career, concluding with the words:—

"In these volumes we hope you will find the kind of offering from your fellow-workers which will please you best; immaterial offerings indeed, but such as may outlive a more material gift. As to you we owe much of the inspiration of these essays, and as in many of their subjects you have taken a bountiful part, so by them we desire to give some form to our common interests and affections.

We pray that health and strength may long be spared to you and to her who is the partner of your life; and that for many years to come you will abide in your place as a Nestor of modern Oxford, as a leader in the van of Medicine, and as an example to us all."

Sir William Osler, in responding to the gift, recalled his own vagrant career—as a student in Toronto, Montreal, London, Berlin, and Vienna, as a teacher in Montreal, Philadelphia, Baltimore, and Oxford. Loving the profession of medicine and believing ardently in its future, he had been content to live in it and for it. We may recall his own words spoken 14 years ago in taking leave of his friends in the United States:—

I have loved no darkness,  
Sophisticated no truth,  
Nursed no delusions,  
Allowed no fears.

In the spirit of equanimity, which he then praised, he has borne success with humility, the admiration of his friends without pride, and has stood the test of sorrow with unflinching courage. The 14 years among us have brought Sir William Osler in full measure the affection of us all.

### DEGENERATION AND REGENERATION IN THE PERIPHERAL NERVES.

Professor Onari Kimura, of the Pathological Institute of the Imperial University at Sendai, Japan, has published an elaborate monograph<sup>1</sup> on degeneration and regeneration in the peripheral nerves, with especial reference to non-traumatic cases and experimental beri-beri, embodying the results of a long series of investigations on non-traumatic "neuritis." His researches were conducted on some 20 fowls and pigeons, in which typical "polyneuritis" was produced by feeding on polished rice for varying periods and in varying combinations, fully detailed in the monograph. By way of comparison, some 16 dogs and guinea-pigs were subjected to nerve section with immediate enclosing of the central end in an animal

<sup>1</sup> Mitteilungen a. d. pathologischen Institut der Kaiserlichen Universität zu Sendai, Japan, 1919, erster Band, erster Heft, pp. 1-160.

membrane filled with fresh blood, or the cut ends were placed in apposition in various ways—e.g., in one case they were surrounded by a mass of brain-substance taken fresh from another guinea-pig. The minute histological investigation of a human case of acute tuberculous polyneuritis and of progressive hypertrophic interstitial neuritis (Dejerine-Sottas) was also undertaken. As Professor Kimura intends to deal with the traumatic material in a subsequent communication, his allusions to it are brief, but he points out that regeneration in section cases is different from what obtains in non-traumatic cases, to which he devotes almost the whole of his paper. The pathological changes in the nerves and muscles of birds fed on polished rice are essentially of a regressive-degenerative character. In the muscles simple atrophy and fatty degeneration are the chief changes, but they are not of primary significance, for often within one week of the resumption of normal feeding wasted muscles recover their ordinary volume and apparently also their full functional power. The severity of the anatomical changes in the peripheral nerves, in experimental "rice-neuritis," bears no constant parallel relationship to the clinical symptoms. In their essentials they consist of a pure degeneration; in no instance did Professor Kimura find any sign of alterations of an inflammatory nature. Degeneration does not by any means always commence at the periphery of the nerve fibres; on the contrary, it may appear anywhere along the course of a nerve, sometimes at different levels in different fibres of the same nerve. Further, normal and degenerated fibres are seen side by side. The suggestion is made that experimental "neuritis" is a general affection of the nervous system, with local lesions at sites that are somehow predisposed. Lower extremities are much more usually affected than upper, with special incidence on the peroneal nerves. The first recognisable sign of degeneration is in the axon, frequently noted when the myelin sheath is still intact, nor does it necessarily progress distally by a mere Wallerian process, for the morbid agent may attack spots beyond the original lesion. Once the nerve fibre gets to the stage of complete myelin degeneration no axon can be found in it; in fact, the latter disappears before any complete break-up of myelin. The myelin fragments are, according to all appearance, absorbed *in situ* after being dissolved or otherwise chemically modified by some (? fermentative) function of the cells of the sheath of Schwann, or stream in this dissolved state towards lymph and venous channels; in the human cases, however, there was evidence of direct phagocytic activity for the scavenging of some at least of the degenerative products. When a fibre in a state of complete myelin disintegration is seen to contain within its neurilemma an axon, such axon, according to Professor Kimura, is invariably a new formation—i.e., a regenerated axon. To the problem of regeneration in non-traumatic "neuritis" he devotes an important part of his research. His view, supported by much histological evidence, is that the way is paved for the new axons by protoplasmic prolongations of the cells of the neurilemmal sheath, that these link up to form more or less "solid" protoplasmic paths, filling the otherwise nearly empty fibre. In or through this protoplasm the new axon makes its appearance, either by direct outgrowth from the proximal end, or—a very important alternative—by differentiation from this

ribbon-like protoplasm, beginning at the end nearest to the old axon-stump, and spreading link by link peripheral-wards. It is commonly a simple, smooth, delicate axon, with neither whorl nor end-bulb formation on its course, thereby differing from what is seen in the majority of cases of regeneration after trauma. Much importance in this matter is attached by the author to the intactness of the neighbouring connective tissue supporting the nerve. For the equally interesting question of the origin of the new myelin formation these researches of Professor Kimura unfortunately do not serve; he merely indicates the possibility of part of the protoplasmic bridges within the fibre sheath being allocated to that purpose. It is to be regretted, also, that he modestly considers his experimental material too meagre for any exhaustive contribution to the problem of the pathogenesis of beriberi, or "rice-neuritis," and contents himself with a review of the literature and present state of knowledge on this vexed question. He remarks with justice that little enough attention has been paid to the actual pathology of the deficiency diseases, and is not clear that the "monophagismus" group of beriberi, scurvy, Barlow's disease, and pellagra contains conditions essentially alike in their pathogenesis. Whether "ein schädliches plus" beyond mere partial starvation is essential Professor Kimura does not allow himself to say, but he quotes with approval the opinion of Eijkman—which for that matter had been expressed before—that absence of some essential element in food may allow the development of some nerve poison to which the symptoms are attributable. The monograph is illustrated with admirable coloured drawings, and micro-photographs reproduced in collotype, and there is a very long bibliography.

#### INSURANCE FOR MEDICAL MEN.

THE Managing Committee of the Medical Insurance Agency met last week and found itself able to make substantial interim allotments, amounting to £455—£125 to the Royal Medical Benevolent Fund, £125 to the Royal Medical Benevolent Fund Guild, £105 to Epsom College Royal Medical Foundation, and £100 to the Royal St. Anne's School. In this way the committee was fulfilling one of its prime objects. For the Agency, when founded 12 years ago with the intention of assisting medical men to obtain the best terms of insurance of all kinds, has from the first kept in mind as one of the chief reasons for its existence the practical aid of the benevolent institutions of the profession. The Royal Medical Benevolent Fund is the most largely benefited of such institutions in the recent distribution, but its record deserves that this should be so, while its offspring, the Guild, is doing most admirable work, the special feature here being the personal interest of individual ladies in the work. It has seemed to the Agency that one of the most practical means it could take to help less fortunate members of the profession was to contribute to the education of children. This it has done by subscriptions to Epsom College, where boys are received on the foundation, and to the Royal St. Anne's School, where girls obtain an excellent education. This benevolent side of the Agency's work has commended it to many members of the profession, though not to so many as might have been expected to resort to it. Last year the total

distributed from the Agency's medical benevolence account was £1002 10s., including contributions of £150 to the War Emergency Fund of the Royal Medical Benevolent Fund, and £100 to the Belgian Doctors' and Pharmacists' Relief Fund. At the same time the insurers received an advantage by the return out of the commissions received by the Agency of certain sums which in 1918 totalled £697. Since the foundation of the Agency £7200 have been returned in this way to insurers, a sum which represents a direct saving to the profession. The Agency is not bound to any particular companies or forms of policy, and is able to advise medical practitioners contemplating insurance as to the best form of policy to suit their particular conditions. The life insurance business conducted through the Agency is considerable, and it is confidently anticipated that as the conditions disturbed by the war become more stable this form of business will largely increase. The insurance of motor-cars is growing into an extensive branch of energy; in spite of the difficulties in the way of motorists created by the war and the shortage of petrol and of cars the number of motor insurances has increased, and experience has proved that the Agency, owing to the amount of business it conducts in this direction, is able to assure to its clients that their claims shall be promptly and generously met. In presenting the financial report the chairman, Dr. G. E. Haslip, was able to speak in the most hopeful terms of the future of the Agency, and mentioned that vacancies, due to deaths of several members of the committee, had been filled by the election of Dr. E. Weaver Adams, Dr. H. A. Des Vœux, Lieutenant-Colonel R. H. Elliot, I.M.S., Dr. R. A. Gibbons, and Dr. R. Langdon-Down.

#### PENTOSURIA.

THE occurrence of pentoses in the urine is not so rare an event as is commonly supposed. Pentosuria is not necessarily associated with any morbid symptoms, and does not of itself call for any particular treatment; the importance of the condition arises from the fact that its presence may lead to a hasty diagnosis of diabetes, with consequent dietetic restrictions which are unnecessary. Two distinct types may be recognised: (1) the alimentary form, in which the sugar is l-arabinose and the urine rotates polarised light to the right; (2) true or essential pentosuria, in which the sugar is usually i-arabinose and the urine is optically inactive, unless some other sugar is present as well. Alimentary pentosuria is apt to cause mistakes in diagnosis, especially at this time of the year when fruit is being eaten more extensively than at other seasons. The tolerance limit for pentoses is small, about half a gramme, and even in healthy people a surfeit of cherries will cause the appearance of the sugar in the urine. Plums, gooseberries, strawberries, apples, and other fruits in sufficient amount may give rise to a similar result. The amount of sugar excreted is usually small, 0·5 per cent. or under, and as arabinose does not reduce as readily as dextrose the reaction is delayed and is often of a peculiar type. When, for example, the urine is added to Fehling's or Benedict's solution and boiled no change occurs for a time, but after continued boiling the colour of the solution suddenly changes to green, no turbidity occurring even when the heating is prolonged. A small percentage of dextrose or other reducing substance may give a similar result.

More characteristic is the orcin reaction, best carried out in the form of Bial's test. 4–5 c.cm. of Bial's reagent (0·5 gr. orcin, 250 c.cm. fuming hydrochloric acid, sp. gr. 1·195, and 12 drops of liq. ferri perchlor.) are heated to boiling in a test-tube and 1 c.cm. of the urine added; on standing a green-blue colour develops when a pentose is present. If the solution is cooled, extracted with amyl alcohol, and the extract examined with the spectroscope, it shows a band between the red and yellow (C and D). Glycuronic acid may give a similar reaction, but it also gives Tollen's naphthol-resorcinol test. The most conclusive evidence is furnished by preparing the diphenylhydrazone with a melting-point of 216–218° C. for the l-arabinose derivative and 204–205° C. for the i-arabinose compound, and the parabrom-phenyl-osazone which melts at 196–200° C. in the case of l-arabinose and 200–202° C. for the inactive form. As pentoses are not fermented by yeast the reducing power of the urine in cases of pure pentosuria is not impaired by mixing it with yeast and standing in a warm place for 24 hours.

#### PRACTICAL ISSUES ON THE ALCOHOL QUESTION.

WE welcome the scientific investigation of alcohol with reference to practical issues. No one drinks a dilution of pure alcohol and water, and yet hitherto, whilst interesting evidence has been accumulated, physiological experiments have, in the main, been based not on the actual beverages consumed by the public, but literally on  $C_2H_5OH + H_2O$ . That formula does not by any means present the story of such beverages as claret, sherry, port, beer, champagne, and so forth, none of which is a mere dilution of pure alcohol, and it is well known that these various alcoholic beverages differ in their effects. The effervescent wine champagne, for example, has a different effect from claret, though both contain the same amount of alcohol. There are important varying factors in the numerous alcoholic beverages consumed by the public which must count in regard to their effects. A mixture of whisky and water, for example, is below the specific gravity of water, whilst wines and beers are above this point on account of the solid matters in solution. Osmotic pressure must therefore vary, and with it the rate of diffusibility of the alcohol.

In an important investigation undertaken for the Medical Research Committee by Dr. Edward Mellanby,<sup>1</sup> bearing on the absorption into, and disappearance from, the blood of alcohol under different conditions, these points find interesting illustration. It is shown that differences in intensity of intoxicating symptoms obtained by taking the same amount of alcohol in one or several drinks depend on the type of beverage drunk and the interval between the drinks. Foodstuffs inhibit intoxication in consequence of their action in delaying the absorption of alcohol from the alimentary canal. The most effective inhibitor is milk, the action of which appears to be dependent to some extent on its fat content. Its specific influence in delaying absorption more than counterbalances its general effect as a fluid, and Dr. Mellanby comments upon the striking differences observed in the effects of a dose of alcohol when given two hours after the consump-

<sup>1</sup> Special Report Series, No. 31. National Health Insurance, Medical Research Committee: Alcohol: Its Absorption into, and Disappearance from, the Blood under Different Conditions. London: Published by His Majesty's Stationery Office.

tion of half a litre of water and after half a litre of milk respectively. In the first case a dog may become incapable of standing or walking, in the latter case it may show no sign whatever of unsteadiness. Whisky is found to be more intoxicating than stout, partly because of its greater concentration of alcohol, and partly because stout contains something which inhibits the absorption of alcohol to some extent. These results are interesting in discussing the factors influencing intoxication. It is found that intoxication is related to the amount of alcohol in the blood and probably to the rate of accumulation in the blood. Dilute solutions of alcohol are less intoxicating than strong solutions containing the same amount of alcohol, the difference becoming more marked the greater the quantity of alcohol consumed and the greater the dilution. These results have an important bearing on the question of what constitutes an intoxicating liquor, a question which is being fought out in the U.S. courts in connexion with the legality of the sale of 2.75 per cent. (alcohol) beer under prohibition. Dr. Mellanby's investigation was confined to the use of dogs as subjects, but the various factors shown to affect the results in a dog are likely to have a corresponding influence in man, and similar experiments so far being carried out on human beings indicate that the results are strictly comparable. There is one difference, however, noted. The hind legs of a dog are the first to show weakness, and it is this which makes it more difficult for a dog to stand still than to walk when intoxicated. In other words, in walking the weakness of the hind legs is compensated for by the front legs and the muscles of the other parts, and collapse prevented. In man the whole support of the body depends upon the legs, and the base of the standing man is relatively much smaller than that of the dog. Consequently, balance is a more difficult matter in an intoxicated man, and therefore unsteadiness is a more predominant feature in the complete picture.

The report is one of the best contributions on the practical side of the question that has been issued, and the evidence that the effect of alcohol is cumulative because its disappearance from the blood is remarkably slow is not the least important observation made—apparently it makes no difference whether a given amount of spirit is taken in one dose or in divided doses at intervals which may extend to two hours.

#### THE CONSULTATIVE COUNCILS OF THE MINISTRY OF HEALTH.

THE draft orders establishing Consultative Councils under the Ministry of Health for England and Wales are now being issued. There are five of these Councils, four for England and one for Wales. The English Councils are to give expert advice in connexion with: (1) Medical and allied services; (2) local health administration; (3) National Insurance; and (4) general health questions. Each English Council will be composed of 20 members, and the Minister and Parliamentary Secretary to the Ministry will be respectively President and Vice-President. The Welsh Council, with the same ex-officio officers, will consist of 30 members chosen to give advice under all four of the English sub-headings. The period of office is for three years, and during the first three years one-third of the Council will retire by lot, but can be reappointed for one further term of three years. The personnel will consist of women as well as men.

#### ENCEPHALITIS LETHARGICA.

DURING the past year reports have been received which show that cases with the symptomatology of encephalitis lethargica have occurred in many countries. There appears to be practical unanimity that the disease is to be regarded as distinct from the encephalitic form of poliomyelitis. Many observers are of the opinion that it is a disease allied to poliomyelitis; while others, mainly those who have made a special study of the history of the disease, incline to the view that encephalitis lethargica is associated in some intimate causal manner with influenza.<sup>6</sup> The latter point out that previous recorded epidemics of lethargy have been associated in point of time with epidemics of influenza, and they suggest that an attack of influenza either predisposes the patient to the lethargy or in some unexplained way activates the virus of lethargic encephalitis. The symptomatology of the recorded cases is the fairly constant one which is already familiar to readers of THE LANCET. The various epidemics differ, however, in the severity of the individual attacks, and particularly in the mortality which, in the case of the Australian epidemic, was as high as 70 per cent. The pathological reports on the fatal cases show constant involvement of the basal ganglia and the pons by an encephalitic process, characterised by well-marked perivascular lymphocytic infiltration with occasional venous thrombosis and necrosis of the brain substance. The severe cases show generalisation of this process in the central nervous system.<sup>4</sup> Inoculation experiments were particularly striking in the case of the Australian epidemic. The virus produced typical lesions, not only when inoculated into monkeys, but also on injection into sheep and into a horse and a calf. Herein it differed markedly from the virus of poliomyelitis, to which the monkey alone has been proved to be susceptible.<sup>5</sup> In another group of cases, on the other hand, experimental inoculation produced clinical and pathological evidence that the disease was acute poliomyelitis with an unusual distribution of the lesions.<sup>2</sup> On the whole, it would appear that while the symptomatology of encephalitis lethargica may occur as a result of the lesions of epidemic poliomyelitis, yet there exists a disease *sui generis* which produces such symptoms as a constant feature, owing to the regularity with which it involves the basal ganglia. Further light on the symptomatology of the disease was thrown by Dr. E. Farquhar Buzzard in his paper read before the Neurological Section of the Royal Society of Medicine on July 10th. In a considerable number of cases which he put on record the initial stage, presenting cranial nerve palsies associated with lethargy, was followed by the appearance of various involuntary movements of the face, tongue, and limbs. The character of these movements was athetoid, with some features strongly reminiscent of chorea, but a general characteristic of all was the absence of interference with the due performance of voluntary movements. In this they resembled the involuntary movements seen in paralysis agitans, and, indeed, in one of the cases described by Dr. Buzzard the aspect of the patient suggested this diagnosis. As is well known, the lesion of Parkinson's disease is localised in the basal ganglia, and cases of disseminated sclerosis in which the patches occur in the same region exhibit sleepiness and drowsiness to a marked degree. It appears, therefore, that lethargy may take its place

among the true localising signs of cerebral lesions. Such being the case, it is to be expected that any disease producing a lesion in this region may cause lethargy. As Sir Thomas Barlow pointed out in the course of the discussion, one of Dr. Buzzard's cases might well have been a case of measles with encephalitis as a complication. So far during this year true encephalitis lethargica has appeared only sporadically, and under such circumstances the separation of a disease with such a complex symptomatology presents great difficulty. Dr. Buzzard indicated the importance of the further development of our knowledge of filter-passing organisms in connexion with diseases in this category.

## TREATMENT OF ANTHRAX BY LOCAL INJECTION OF SERUM.

In the *American Journal of the Medical Sciences* for June Dr. Joseph C. Regan and Dr. Catherine Regan have reported a case of anthrax which, in addition to other features of interest, seems to indicate the value of a new method of treatment—the local injection of anti-anthrax serum. A man, aged 26 years, was admitted to hospital on Nov. 21st, 1918, as a case of parotitis. On the 18th, while shaving, he cut himself on the right side of the neck. He lathered soap over the wound with a new shaving brush which he had washed and placed in boiling water. Next day about noon he complained of headache, backache, and pains all over the body. Towards evening the neck became stiff, especially on the right side, so that it hurt him to turn his head. This he attributed to a small pustule which had developed at the wounded spot. During the night he had a chill and felt feverish. On the 20th swelling of the neck was more marked and was tender. On the 23rd he came under observation. His voice was hoarse. The throat was congested. Over the right interscapular region a few moist râles were heard on inspiration. On the right side of the neck,  $1\frac{1}{2}$  in. below the angle of the jaw, was a considerable swelling with a pustule about 25 mm. in diameter in the centre, like a vaccination lesion on the ninth day. In the centre of the pustule was a black depressed eschar, surrounded by an elevated white border. At the outer margin of the eschar were a number of small elevations resembling vesicles, which discharged continuously serous fluid. The surrounding tissues were very cedematous. Smears and cultures were taken from the ulcerative surface, exposed by lifting the margin of the eschar, and showed anthrax bacilli. This was verified by inoculation of a mouse. A culture from the patient's blood was sterile. On the 24th, at 10 A.M., 48 c.cm. of anti-anthrax serum were injected into the muscles of the right buttock, and in the evening 10 c.cm. into the indurated tissues around

the pustule. From 99° F. at 8 A.M. the temperature rose to 101° at 8 P.M., and returned to 99° on the following morning. This was regarded as a serum reaction. On the 25th the oedema had slightly extended, and the lesion seemed more definitely elevated. 30 c.cm. of serum were injected into the right buttock, and 10 c.cm. into the region around the pustule. On the 26th the inflammation and swelling rapidly subsided. On the 27th the pustule had shrunk considerably and lost its red areola. The most marked swelling was localised in a mass of glands below the angle of the jaw. Twelve c.cm. of serum were injected in their neighbourhood. On the 29th another intramuscular injection of 30 c.cm. was given and the glandular swelling subsided rapidly. Recovery ensued. The anthrax bacillus was cultivated from the shaving brush. Only serum treatment was used. Its success rendered excision of the lesion unnecessary. The local injection of serum does not appear to have been previously tried. The mildness of the attack, despite the situation of the pustule in the neck, is noteworthy.

## MEDICAL BOARDS OF THE MINISTRY OF PENSIONS.

MEDICAL practitioners wishing to serve on the Boards of the Ministry of Pensions, and especially those who have had practice and experience in the diagnosis and treatment of war diseases such as trench fever, dysentery, malaria, &c., are requested to communicate with the Commissioner of Medical Services of the Region in which they reside. The names and addresses of the Commissioners and the boundaries of their Regions are given below:—

London and South-Eastern Region: Dr. H. J. Neilson: Hotel Windsor, Victoria-street, S.W. 1. County Boundaries: The City of London and Metropolitan Police Districts, and the counties of Kent, Surrey, and Sussex.

Eastern Region: Dr. T. Basil Rhodes, 80, Westbourne-terrace, Paddington, W. 2. County Boundaries: Norfolk, Suffolk, Cambridgeshire, Oxfordshire, Huntingdonshire, Bedfordshire, Berkshire, Buckinghamshire, Northamptonshire, Leicestershire, Rutlandshire, Hertfordshire, and Essex (except the portion of the two latter included in London and South-Eastern Region).

South-Western Region: Dr. J. Young, 5A, Union-street, Bristol. County Boundaries: Gloucestershire, Wiltshire, Dorset, Somerset, Devonshire, Cornwall, Hampshire, Isle of Wight.

West Midland Region: Dr. E. R. Hill, Queen's College, Paradise-street, Birmingham. County Boundaries: Staffordshire, Shropshire, Herefordshire, Worcestershire, and Warwickshire.

East Central Region: Dr. Gibbs Lloyd, Acting Commissioner, Basinghall Buildings, Basinghall-street, Leeds. County Boundaries: Yorkshire (except the Cleveland district on the north, which is included in Northern Region, Middlesbrough Area), Derbyshire (except district included in Chester (new)), Nottinghamshire, and Lincolnshire.

North-Western Region: Dr. A. H. Williams, 1, North-parade, Deansgate, Manchester. County Boundaries: Lancashire, Cheshire, Isle of Man, and portion of Derbyshire embracing Glossop and New Mills.

Northern Region: Dr. W. Lloyd Reade, 47, Pilgrim-street, Newcastle-on-Tyne. County Boundaries: Northumberland, the town of Berwick, Durham, the Cleveland district of Yorkshire, Cumberland, and Westmorland.

Welsh Region: Dr. Bickerton Edwards, 30, Park-place, Cardiff. County Boundaries: The whole of Wales and Monmouthshire.

Scottish Region: Dr. G. H. Gibson, 59, Cockburn-street, Edinburgh. The whole of Scotland.

Irish Region: Dr. D. A. Carruthers, 41, Upper Fitzwilliam-street, Dublin. The whole of Ireland.

It is understood that the remuneration will be 1 guinea per session of 2½ hours for ordinary members of the Board and 2 guineas per session for specialist members of the Board.

### A NATIONAL COLLECTION OF WAR SPECIMENS.

As our readers are already aware, the Council of the Royal College of Surgeons of England, at the request of the Army Council, placed its Museum, workrooms, and staff at the disposal of the Royal Army Medical Corps at an early phase of the war for the purpose of building up a national collection to represent the injuries and diseases suffered by soldiers under modern conditions of warfare. From the conservator's annual report, dealing with the welfare of the Museum during the past 12 months, we learn that altogether 4000 specimens have been received, chiefly from hospitals in France, although a representative series was also obtained from base hospitals in the Eastern Mediterranean. Over 1200 of these specimens have already been examined, mounted, described, and placed on exhibition in the Museum. At the conclusion of fighting plans had to be considered regarding the future of the War Office or national collection: (1) as regards its housing and upkeep; (2) as regards its completion. The future home of the collection remains unsettled, the War Office having no building at its disposal sufficient to accommodate a collection which requires the floor-space of three of the larger rooms of the Museum for its display. As these rooms are now needed for their pre-war purposes, the Council of the College has consented to devote the floor-space and galleries of one room for the display of the national collection until the War Office has determined on its future home and upkeep. Whatever plan may be adopted it is to be hoped that the collection will be placed where it may be available for study by civilian surgeons as well as by officers of the Royal Army Medical Corps—that it may, indeed, form a bond between the civil and military branches of the profession. The main burden of preparing the collection—certainly the most extensive and instructive of its kind ever assembled—has fallen on Professor S. G. Shattock and Mr. Cecil Beadles, and arrangements are now being made, so we are given to understand, between the Director-General of Army Medical Services and the Council of the College to secure the services of these two gentlemen in completing the collection—a task which will entail at least two more years of labour. Not only has the Museum of the College served the needs of our own Medical Service, but also those of Canada, Australia, and New Zealand. Of the 4000 specimens forwarded to the Museum about 1600 of them were collected by the Colonial Medical Services, and these have recently been removed from the Museum to form teaching collections in Canada, Australia, and New Zealand. Thus, in spite of a much depleted staff, the Museum of the College was able to render a considerable service by securing definite and permanent records of our medical and surgical experience of modern warfare. Further, we learn from the conservator's report that the Museum is being gradually restored to its pre-war state, but that it will not be fully open for study until October next. The indiscriminate bombing carried on by the enemy made it necessary to remove all the spirit specimens—some 12,000 in number—to the cellars in the basement of the College, and their return is possible only when the War Office specimens have been arranged in the room now set aside for their display. The opportunity has also been taken of effecting some very desirable alterations in the arrangement of

the contents of the Museum. In spite of the war we are glad to note that many valuable donations have been made to the collection, and that researches of value have been carried out. Mr. Alban Doran continues to compile a catalogue of the surgical instruments, which will form a standard history of surgical invention—one which, we hope, the Council of the College may see its way to publish some future day.

### MEDICAL AID FOR CROFTERS AND COTTARS.

IN one important section of Great Britain a form of State medical service has been a going concern for a number of years, and deserves the close attention of all those interested in the reconciling of private and State-subsidised practice. The medical service now obtaining in the Highlands and Islands of North Britain is described by the Statutory Board, which has charge of it, as a spontaneous growth combining in certain districts the efficiency of a private or competitive service with the stability of an official service provided by the State. The Board constituted under the Highlands and Islands Grant Act of 1913 for the period of four years has been continued on account of war conditions, and has just presented its fifth report. Of the schemes prepared and approved in 1914 by the Secretary for Scotland only those involving grants to medical practitioners and to district nursing associations have come into effect. The scarcity both of doctors and nurses was naturally enhanced during the year 1918 covered by the present report. The serious situation created by the influenza pandemic was only met by the high sense of individual duty prevailing in the service. The medical service, which has now stood the test of three years' experience, covers 143 practices, nine of which in normal times require the coöperation of two doctors. In spite of depleted staff the year 1918 saw an increase of 7 per cent. in the travelling and of 21 per cent. in the number of visits over the preceding year. We note, however, that the increase is confined to patients coming within the Board's scheme, and is balanced by an almost corresponding decrease in respect of private practice. In point of fact, at the present time about four-fifths of the entire medical service rendered to the crofters and cottars is subsidised or maintained from public sources. In some of the poorer districts the amount of private practice is now almost negligible. Travelling grants enable practitioners to visit distant patients at low uniform fees; these grants in 1918 amounted, in the case of poorer practices, to a sum producing a net income of about £360 a year, and in the aggregate to some £32,000. The nursing service was recently referred to by Mr. Munro, Secretary for Scotland, in reply to a question in the House of Commons. A scheme at present before the Treasury would have the effect of increasing the nurses' remuneration by approximately 30 per cent. on the pre-war figure. The number of nursing associations on the grant list is stated in the report to be 38 and the total number of nurses employed 98, of whom 49 are fully trained. The cost of this service for the year in question amounted to £4000. Partly trained nurses have been perforce accepted during the war years, but some of these have already been replaced by others with higher qualifications, and on the new county (as opposed to the parish) basis specialised schemes

of public welfare are contemplated, in addition to the general nursing work of the area. £130-£135 for a fully trained nurse and £100-£110 for a midwife or nurse with intermediate qualifications are the rates of remuneration suggested by the Board as meeting present requirements. Although the remaining schemes under the Board's mandate have been practically in abeyance during the war, a study of the report will not fail to bring home to the careful student the lesson of what can be attained by a judicious blending of public and private effort.

#### THE CARRIER AND THE ATYPICAL CASE.

MUCH is to be gained from an extended study of those diseases which tend to appear and to spread in closely aggregated communities. Among such diseases cerebro-spinal fever occupies a prominent place. In the present issue of THE LANCET we publish an article by Lieutenant-Colonel J. Dorgan, R.A.M.C., which raises many points of importance, especially with regard to the administrative methods to be adopted when dealing with an outbreak among a population living under army or institutional conditions. His contention is that the atypical and unrecognised case is the factor of primary importance in the spread of the disease, while the healthy carrier is relatively innocuous. He supports his view with circumstantial and statistical evidence, laying stress upon the acknowledged fact that the healthy carrier is seldom known either to develop the disease himself or to transmit it to others. Proof of transmission is, in the nature of things, very difficult to establish, since the carrier is usually discovered after the case of infection. But the occurrence in an epidemic of atypical infections due to the meningococcus, as adduced by Dr. Dorgan, is closely paralleled by the well-attested occurrence of atypical cases in the course of any considerable outbreak of diphtheria, or, indeed, by our knowledge of almost all epidemic diseases. It would be of interest to know how the meningococcus carrier-rate among patients suffering from such atypical attacks compares with that in healthy contacts and non-contacts living in the epidemic area in view of the wide differences which have been demonstrated under similar circumstances in other diseases. While Dr. Dorgan regards the susceptibility of the individual rather than the virulence of the organism as the determining factor in the occurrence or non-occurrence of meningitis in a person exposed to infection, his article may be read in conjunction with the concluding instalment of the Goulstonian lectures on the Spread of Bacterial Infection, which appears in our present issue. The primary importance of persons suffering from atypical infections in the spread of cerebro-spinal fever would agree well with Dr. W. W. C. Topley's suggestion as to the possible mode of origin of an outbreak of disease. In his view a variation in the biological properties of the parasite would be the essential factor, and the high potential infectivity of the atypical case as compared with the healthy carrier would find its explanation in the fact that the former was harbouring the more infective organisms. Either view would depreciate the general application of measures of isolation in dealing with healthy carriers, while emphasising the crucial importance of improving environmental conditions, more especially by the elimination of overcrowding and the provision of free ventilation.

## BRITISH FEDERATION OF MEDICAL AND ALLIED SOCIETIES

(LATE MEDICAL PARLIAMENTARY COMMITTEE).

At the Conference between the Medical Parliamentary Committee and the representatives of other organisations held on May 2nd<sup>1</sup> it was decided that the giving of effect to seven resolutions then passed should be left to the existing provisional committee. On Friday last, July 11th, at a meeting held in the College of Ambulance, this provisional committee submitted its report.

Dr. ARTHUR LATHAM, honorary secretary of the Medical Parliamentary Committee, was unanimously elected to the chair, when he explained the absence of Sir Watson Cheyne, who had hitherto occupied the position of chairman. Owing to ill-health and the pressure of his Parliamentary duties Sir Watson Cheyne found himself unable to give the necessary time to the affairs of the organisation, and he had written regretting the necessity for his retirement from the office of chairman, which was entirely due to physical disabilities and not to any differences of opinion. He found it inadvisable to accept any outside work, especially in the present conditions of travelling, and he was able to do his Parliamentary work by attending to that and that alone. He was pleased, he added, to leave his name on the committee. In view of Sir Watson Cheyne's resignation, said Dr. Latham, the provisional committee had invited Sir Malcolm Morris to be chairman, and he had accepted the position, but was unable to preside at the present meeting owing to an important engagement previously entered into. Dr. Latham read a letter from Sir Watson Cheyne expressing his pleasure that Sir Malcolm Morris should take his place, and in this letter he indicated as pressing matters in which the activities of the organisation would be most useful—the Bill just introduced to raise the insurance limit to £250, and the Medical Service Bill which Dr. Addison would bring in next winter.

#### *The Future Policy before the Meeting.*

Dr. Latham then explained the policy of the Medical Parliamentary Committee, which was intended to be constructive by collecting the opinions of all branches of the medical profession on matters of public health. This idea was submitted to the Conference on May 2nd, when certain resolutions were passed, and a provisional committee was empowered to put these resolutions into shape, and form a new federated body. So far no less than 47 societies had accepted representation on this committee, and it was hoped that the number would be increased when the ideas of the committee were better understood. However, he thought that to persuade the representatives of 47 societies associated with and allied to the medical profession to sit round one table was something of an achievement. The business of the present meeting would be the appointment of an executive in order that work might be started at once, while some additional members would have to be co-opted and the question of the title of the organisation discussed. The name Medical Parliamentary Committee had unfortunately given rise to the idea that the body was going to do something which it never intended to do. The name savoured too much of politics. Lastly, it would be necessary to discuss the question of finance.

The minutes of the meeting on May 2nd were taken as read, when some discussion arose respecting the hour of meeting, as the time most convenient to London and country members respectively clashed, while a time that would be generally convenient to the medical profession might not suit the representatives of allied bodies. It was felt that the convenience of provincial representatives should be considered in order that the organisation might be enabled to get the views of members throughout the country. On the suggestion of the Chairman, the matter was left in the hands of the executive committee.

#### *The Societies Represented.*

Dr. N. HOWARD MUMMERY, the honorary organising secretary of the Medical Parliamentary Committee, then read

<sup>1</sup> THE LANCET, May 10th, p. 808.

the names of the societies attending and their representatives as follows:—

Association of Certifying Factory Surgeons (Incorporated).  
Association of Medical Officers of Health.  
Association of British Postal Medical Officers.  
Association of Panel Committees.  
Association of Public Vaccinators.  
Association of School Medical Officers of Scotland.  
Birmingham and District General Practitioners' Union.  
British Dental Association.  
Brighton and District Medico-Chirurgical Society.  
British Science Guild.  
Central Committee for the State Registration of Nurses.  
College of Nursing, Ltd.  
Council of British Ophthalmologists.  
Eastern Valley Medical Association.  
Harveian Society.  
Harrowgate Medical Society.  
Incorporated Midwives Institute.  
Infirmary Medical Superintendents' Society.  
Irish Medical Association.  
Leeds and West Riding Medico-Chirurgical Association.  
London Dermatological Society.  
Manchester Odontological Society.  
Medical Officers of Schools' Association.  
Medical Women's Federation.  
Medico-Psychological Association of Great Britain and Ireland.

Medico-Political Union.  
Metropolitan Police Surgeons' Association.  
Midland Medical Society.  
Midland Obstetrical and Gynaecological Society.  
National Association for the Prevention of Tuberculosis.  
National Council for Combating Venereal Diseases.  
National Medical Journal.  
National Medical Union.  
New London Dermatological Society.  
North London Medical and Chirurgical Society.  
North of England Tuberculosis Society.  
Pathological Society of Great Britain and Ireland.  
Pharmaceutical Society of Great Britain.  
Physiological Society.  
Poor-law Medical Officers' Association.  
Reading Pathological Society.  
Royal Institute of Public Health.  
The Royal Society of Medicine.  
Scottish Union of Medical Women: Eastern Branch and Western Branch.  
South-West London Medical Society.  
Southampton Medical Parliamentary Committee.  
State Medical Service Association.  
Tottenham Medical Union.  
Tuberculosis Society.

The Council of the British Medical Association had not, he said, sent a representative, but the matter would come up for discussion at the next general meeting of the members.

#### *The Provisional Report.*

The report of the provisional subcommittee was then voted upon paragraph by paragraph, when Dr. A. E. BOYCOTT, representing the Pathological Society of Great Britain and Ireland, remarked that if he voted for or against a proposition he must not be taken as pledging his society. Other representatives being in a similar position, the Chairman was subsequently asked for a ruling on the matter, when he said that what was wanted was the definite opinion of representatives, though this would not necessarily commit their societies. Without such definite opinions the committee could not come to a satisfactory conclusion on any subject, and he thought it was the duty of all representatives to vote on the matter before them. The report ran as follows:—

*Report of the Provisional Subcommittee Appointed by the Medical Parliamentary Committee at the Conference held at the Central Hall, Westminster, on May 2nd, 1919.*

In pursuance of the resolutions passed at the Conference on May 2nd, 1919, the provisional subcommittee have to report:—

1. That the office of the committee has been temporarily established at 20, Hanover-square, London, W.1.  
2. That the subcommittee has met on five occasions for the purpose of deliberation and conduct of business.

The following resolutions, as recorded in the minutes of these meetings, have been passed:—

(a) The appointment of a provisional chairman in the place of Sir William Watson Cheyne, resigned. This office has been offered to, and has been accepted by, Sir Malcolm Morris, K.C.V.O.

(b) The appointment of a provisional organising secretary. This office has been offered to, and has been accepted by, Dr. N. Howard Mummery, who has offered to act in an honorary capacity until the Conference called for July 11th, 1919.

3. That the necessary estimated annual and preliminary expenditure is as follows:—

<i>Annual Expenditure.</i>		<i>Preliminary Expenditure.</i>	
Rent of office ... ..	£200	Office fittings and furniture ... ..	£92
Material and incidental expenses ... ..	300	Expenses of incorporation ... ..	100
Salaries of organising secretary, clerk, and lobby correspondent ... ..	1326		£192
Annual ... ..	£1826		
Total for first year ... ..	£2018.		

4. That in the opinion of the provisional subcommittee the time has now been reached when it is essential to further expansion and increased activities that:—

(i.) The committee should establish a Federation under the title of "The British Federation of Medical and Allied Societies" to carry on the work commenced by the Medical Parliamentary Committee. Only thus can it acquire the financial basis necessary to its further existence.

(ii.) That such Federation should form itself into an incorporated association, limited by guarantee and not having a share capital, under the Companies' Acts, 1908-1917. That it be registered under the Board of Trade (Section 20) with limited liability, without the word "Limited" after its name, but with the word "Incorporated" added. In this form it is expressly laid down that it cannot be considered a "trade-union." That it be registered under the title of "The British Federation of Medical and Allied Societies (Inc.)," late Medical Parliamentary Committee.

5. That the representatives of the affiliated and allied bodies and the coöpted members shall form the Council of the Federation.

6. That an executive committee be elected to carry out the business of the Federation, with power to engage the services of the necessary officers and servants on the salaried list, obtain the necessary permanent officers of the Federation, with power to appoint subcommittees, and to incur the necessary preliminary expenses.

7. That the following financial scheme be adopted and incorporated in the articles of association:—

#### *(a) Entrance fee.*

(i.) For each association, society, or allied body represented on the Council of the Federation a sum of not less than two guineas (£2 2s.).

(ii.) For each coöpted member of the Council of the Federation a sum of not less than two guineas (£2 2s.).

(iii.) At a later date, to be fixed when deemed appropriate by the Council of the Federation, for each directly elected representative of the medical profession a sum of not less than one guinea (£1 1s.).

#### *(b) Annual subscription.*

(i.) That members of each association, society, or allied body represented on the Council of the Federation be asked through the various executives of those bodies to subscribe to the funds of the Federation a sum of not less than half a guinea and thereby constitute themselves members of that Federation.

(ii.) For each coöpted member of the Council of the Federation a sum of not less than two guineas (£2 2s.).

(iii.) Subject to par. 7 (a) (iii.) above a sum of not less than one guinea (£1 1s.).

#### *(c) Guarantee fund.*

To meet immediate requirements credit be obtained from a banker in the sum of two thousand pounds (£2000) secured by the personal guarantee of selected members of the Council of the Federation, or other members who may offer to act in that capacity. Provided that ten guarantors, each in the sum of £200, or 20 guarantors, each in the sum of £100, be the number necessary; or such proportion of each as may be deemed advisable. Such guarantees to be required only until funds are available from entrance fees and subscriptions.

The first sections of the report were passed subject to some discussion.

On par. 4, referring to the change of name, the Chairman said that many people thought the organisation was going to engage in politics, and the name Parliamentary Committee was not understood. The industrial bodies of the country usually called their organisations "federations," and he thought it would make clearer the objects of the present body if the name Federation rather than Parliamentary Committee were adopted. After some discussion the change was agreed to, the Chairman stating, in answer to a question, that the change of name did not imply any change in the policy and objects of the Medical Parliamentary Committee.

#### *The Guarantee Fund.*

On par. 7, dealing with the financial scheme, some discussion arose as to the powers and responsibilities of the various societies represented in regard to the payment of subscriptions by their members, the Chairman pointing out that any society which did not agree with any of the resolutions that might be passed in regard to finance had a perfect right to withdraw. At present the Federation had no money, and it was necessary if work was to be done that there should be a guarantee fund.

Dr. C. BUTTAR said he had hoped that each society would contribute according to membership. As more and more societies joined *6d.* a head would cover the whole of the finances required. As long as the Federation did not appeal, as it ought to do, to each individual of the medical profession, a payment of so much per head per member of a society would be the best arrangement.

Finally, it was decided to leave the matter for the present in the hands of the executive committee to draw up a scheme for raising funds which should be submitted to the various societies asking for an expression of opinion, while at the next general meeting the representatives of these societies should be empowered to vote on a scheme.

A guarantee fund of approaching £1300 was then announced.

#### *Coöption of Members of the Council of the Federation.*

The number of representatives of the Council is 53, and the number of coöpted members 10, of whom 2 may be

engaged in consulting medical practice. The following were accordingly co-opted:—

Mr. J. Y. W. MacAlister.	Mr. E. F. White.
Mr. Frank Coke (Ashford).	Dr. Arthur Shadwell.
Dr. W. Hodgson (Crewe).	Lieut.-Col. F. E. Fremantle.
Sir Thomas Parkinson.	Sir Bertrand Dawson.
Dr. Howard Marshall (Cirencester).	Mr. J. P. Lockhart-Mummery.

#### *The Executive Committee.*

The following Executive Committee of 20 (of whom 4 may be engaged in consulting practice with power to add to their number) was elected:—

Dr. Rashell Davison, Association of Medical Officers of Health.  
 Dr. H. J. Cardale, Association of Panel Committees.  
 Mr. C. F. Rilot, British Dental Association.  
 Sir Ronald Ross, British Science Guild.  
 Mrs. Bedford Fenwick, Central Committee for the State Registration of Nurses.  
 Mr. Comyns Berkeley, College of Nursing, Ltd.  
 Mr. Frank Coke, Medico-Political Union.  
 Miss Rosalind Paget, Incorporated Midwives Institute.  
 Dr. Jane Walker, Medical Women's Association.  
 Dr. R. H. Cole, Medico-Psychological Association.  
 Mr. E. B. Turner, National Council for Combating Venereal Diseases.  
 Dr. Edwin Smith, National Medical Union.  
 Mr. Rowsell, Pharmaceutical Society of Great Britain.  
 Professor Starling, Physiological Society.  
 Dr. A. Withers Green, Poor-law Medical Officers' Association.  
 Dr. W. Pasteur, Royal Society of Medicine.  
 Dr. Chalmers Watson, Scottish Union of Medical Women.  
 Dr. Halliday Sutherland, Tuberculosis Society.  
 Dr. S. Squire Sprigge.  
 Dr. Arthur Shadwell.

#### *Ex-officio.*

Chairman: Sir Malcolm Morris, K.C.V.O.  
 Vice-chairmen: Dr. Arthur Latham, Dr. E. H. M. Stancomb.  
 Hon. Treasurers: Sir Thomas Horder, Dr. J. F. Gordon Dill.  
 Hon. Secretary: Dr. Charles Buttar.

## NATIONAL CONFERENCE ON INFANT WELFARE.

(Continued from p. 78.)

At the afternoon session on July 2nd Dr. RHODA ADAMSON, clinical lecturer in obstetrics at the University of Leeds and honorary medical officer to the Leeds Maternity Hospital, spoke on the subject of the

### *Industrial Employment of Mothers in Relation to Infant Mortality.*

She insisted that the most suitable person to attend to the young child was the child's own mother. Failing which, these duties were best carried out by someone trained in infant care. That if the mother was employed in some industry away from home she had to make some provision for the care of her young children during the hours that she could not be with them, and the well-being of the children depended very much upon the type of care the mother was able to substitute for that of her own. She thought that employment of married women was largely a matter of custom in some localities and hard necessity in others. Some women continued to work after marriage at the same trades that employed them while unmarried because they preferred this type of work to the dull routine of housework to which they were unaccustomed and because they could marry earlier when the house contained two breadwinners. Others, as a matter of course, gave up all active wage-earning employment on a marriage which had been postponed until the husband was able to support a wife and family with his unaided earnings. Others were driven to seek paid employment at some later period after marriage because the family income without their help was not sufficient to maintain it. Under this heading the speaker included widows with insufficient pensions and married women with invalid or lazy husbands. The children of the home-keeping mother were more usually breast-fed during the earlier months of infancy, she said, because, from her point of view, this method was more economical and simpler than any other method. The children of the mothers working away from home were sometimes breast-fed at night and bottle-fed by day, but more usually entirely bottle-fed.

The first method was generally recognised as being the most desirable and to give the infant a far greater chance of life during the early weeks after birth than bottle-feeding with whatever mixture happened to be chosen as a substitute. If the mother was unable to nurse her child the preparation of an artificial bottle-feed required much care and attention; it could not with safety be left to a woman to carry out by the light of nature in a casual way. It was essential, she thought, that the mother should stay at home herself or that there should be adequate provision of well-staffed day nurseries in all areas where mothers of young children were compelled to leave them because of employment away from home. She emphasised the fact that the health of young children was very largely dependent upon their share of fresh air and sunlight and the general cleanliness of their surroundings. So that children living in the country, even though in poor homes, were healthier than those brought up in crowded slum areas, though in such cases the family income might be much greater. In towns, therefore, it was essential that the children should be taken out of doors by their mothers or else placed in an open-air shelter in connexion with some day nursery.

### *The Provision of Nurseries and the Need of a State Allowance for Mothers.*

Failing the general institution of endowment of motherhood and the exclusion of such mothers from industrial employment while in receipt of an allowance, it appeared essential to procure the general provision of nurseries capable of accommodating young children as daily or permanent boarders. Such nurseries were costly to establish and expensive in their upkeep, and no working woman could by her regular payment be expected to defray her share of expense of such a nursery without some additional grant towards the cost from local or central government funds. If, therefore, the State might in either case be expected to contribute towards the expense of maintenance and care of children of the working classes it appeared more reasonable to pay the mother to carry out these duties rather than some other disinterested institution. The speaker suggested that such State allowance should be optional, to be claimed by the mother if she saw fit, and that coupled with its payment should be inspection to ensure that it was being applied for the benefit of the children and incidentally also for the mother. It was well recognised that an infant ran the greatest risk of death during the first three months after birth. Therefore, if some scheme could be devised to make it possible for mothers of children under three months old to remain at home personally to nurse and care for their children a certain saving of infant life might be brought about. The present factory regulations of the Home Office excluded a mother from industrial employment for four weeks after the birth of a child, this exclusion having been enjoined in the interests of the health of the mother, but with this four weeks' exclusion there was no provision whatever for the financial help of the mother to maintain herself and the child, and therefore it possibly involved underfeeding of both mother and child. Personally Dr. Adamson was not in favour of any law or Home Office regulation directed towards the exclusion of all married women with children from industrial employment for any period, however short. She considered that the average mother of young children would prefer to stay at home and look after them if the family income did not need to be augmented by her industrial employment. She thought that the effect of exclusion of such women from factory work would be two-fold, some would practise some form of birth control to avoid the risk of losing their work, and others who had not avoided parenthood would be driven into less well paid employment, such as domestic work, which still necessitated their absence from their home and children.

MISS L. BARKER, O.B.E., of the Training Department, Ministry of Labour, said that mothers were forced into industry by their husbands being: (1) dead; (2) disabled; (3) out of health; (4) of such a low category industrially as to be unable to earn a fair wage; (5) gone away, leaving wife and children; (6) out of employment. She would like to see creches established, with hours to fit those of the working mother, and with rules framed to avoid the ill-effects of broken treatment of child during week-end (overfeeding and the like). Also some sort of centre to which elder children could be sent during out-of-school hours, when

the mother was working. Creches should have a training service or school for nursemaids attached, and the attendance at lectures, needlework classes, &c., of mothers whose children are in residence should be one of the terms under which the child is accepted. Creches or nursery schools might well be centres for antenatal teaching also. Her personal experience was that the health and general physique of children at creches and babies' homes at Woolwich were increased in contrast with those not cared for in this way.

#### *Back-to-back Houses.*

Mrs. HOLDEN (Dewsbury), in emphasising the unhealthiness of back-to-back houses, quoted the following table from a pre-war report of the medical officer of health for Dewsbury:—

	Back-to-back houses.		Through houses.	
	Working.	Not working.	Mothers working.	Mothers not working.
Number of children born ...	108	360	78	5
Number dying under 1 year ...	40	34	6	5
Rate per 1000 deaths ...	370	94	64	

She summed up her arguments against the employment of the nursing mother in industry by stating that first, the strain of the double duty is too much for the mother; secondly, equally important, the atmospheric conditions of a home shut up the greater part of the day are bound to be bad for all, especially the young children.

## MEDICINE AND THE LAW.

### *Medical Fees in Court.*

It was reported recently in the daily press that in an action for damages at Westminster County Court against the London County Council Mr. Blackwell, counsel for a carman, said that a woman doctor from the Royal Free Hospital had been subpoenaed to give evidence. She had been offered a guinea, but wrote that "she could not think of accepting so inadequate a fee." The judge, Sir Alfred Tobin, said he understood from the registrar that the correct fee was one guinea plus travelling expenses, whereupon Mr. Blackwell replied that in this case the expenses would be a few pence. "Fortunately we can get on without her now." His honour is then reported to have observed: "It is a great contempt of court for the lady not to come when proper fee is offered. If any application was made to me to deal with it I should know how to do so. I would deal as severely as I can, for it is most important that justice should be assisted and not impeded." Those who are conversant with county court methods will not too readily assume that learned counsel was correctly instructed when he declared that the lady had been subpoenaed. Many house-surgeons and physicians, before now, have been induced to appear in this species of action, have given really expert evidence, and have failed to receive even the usual fee allowed by the rules. But there is, of course, no legitimate excuse, if a subpoena has been accepted, for failure to appear, save physical disability or the order of a higher court; and a witness who has accepted subpoena must be content to receive the fees allowable by the rules of the particular court, unless the solicitor in charge of the case is willing to pay something more substantial. An unwilling witness may, however, always refuse to attend, save after subpoena, to take the oath unless paid the regulation fee, and, having taken the oath, to testify otherwise than as to the facts unless paid a fee satisfactory to himself.

### *Tuberculosis and Marriage.*

The second trial of the case of *Porter v. Barnard* has ended in a verdict for the plaintiff for £250, the judgment including the costs of both trials. The plaintiff had first met the defendant, who at that time was fourth engineer in a tramp steamer, in Richmond Park. He was then home for a brief period of leave and he invited the plaintiff and her sister to tea. After the acquaintance had been renewed during a later return of the defendant to his home he became engaged to be married to the plaintiff. Before the proposed marriage took place, however, the question of whether the plaintiff was suffering from tuberculosis arose, and the defendant's father, being a medical practitioner, made an examination, from which he concluded that it was undesirable that she should be married. The breaking off of the engagement led to the action for breach of promise of marriage which

has now ended in the plaintiff's favour, medical evidence having been given on both sides as to the safety or otherwise of marriage in view of the condition of the plaintiff's health. She had been under treatment at the Downs Sanatorium, Sutton, for tuberculosis, so that there was evidence of her having at one time suffered from the disease; but the questions left to the jury indicate the facts which Mr. Justice McCardie considered essential to the establishment of the defence set up. The questions left to the jury and the answers given were:—

- (1) "Was the plaintiff suffering from tuberculosis on June 1st, 1918 (the date on which the parties became engaged)?"—"No."
- (2) "Was the plaintiff unfit through tuberculosis to marry either (a) on October 28th, 1918; (b) at Christmas, 1918; or (c) within a reasonable time afterwards?"—"No."
- (3) "Did the plaintiff know on June 1st, 1918, that she was suffering from tuberculosis?" No answer was given to this question, which, it apparently was considered, should be answered if Question (1) had received an affirmative reply.

The case at any rate seems to show that the courts will recognise the undesirable nature of a marriage between persons one of whom is tuberculous, and will regard the breaking off of an engagement between them as justified, but the various aspects of the question would perhaps have been more clearly considered if the facts had been found to justify a judgment for the defendant.

## TUBERCULOSIS.

### *After-care for Consumptives.*

HOWEVER adequate may be the medical treatment provided by county council and insurance committees, there always remains a need for voluntary help in the matter of the care of the tuberculous. Rather than apply for Poor-law relief, many a worker will continue in his employment until medical treatment can be of little use to him, while in cases where medical treatment has already been given a sympathetic interest in his family difficulties from some voluntary committee with a financial backing will often make all the difference between a complete cure and a relapse. The reports of the various care committees in the county of Lancashire show that during the past year 279 patients have been assisted in various ways. Help most frequently takes the form of extra food and clothing. The loan of bedsteads and bedding for those who would otherwise be unable to sleep in separate beds is an important part of the work, but the personal interest of the members of the committee is probably the most important of all, though it does not appear on the balance-sheet.

### *Segregation of Advanced Consumptives.*

At the request of the Southwark borough council the town clerk, the medical officer of health, and the tuberculosis officer have prepared a report on (1) the question of the provision by the State of accommodation other than that provided by institutions maintained by voluntary charitable bodies, in which persons in an advanced stage of consumption can end their days; and (2) the question of compulsory powers being given to local authorities to remove cases where it can be shown that the patients, having regard to their surroundings, are a danger to the health of those with whom they reside. With regard to the first point, the report states that as far back as 1913 at a conference of London sanitary authorities convened by the London County Council, the chairman of the conference drew attention to the necessity for providing "rest homes," and pointed out how undesirable it was that advanced consumptives should be mixed with the more hopeful cases. The only provision made by the State at present is accommodation in a Poor-law institute and a number of beds for discharged soldiers provided by arrangement with the Insurance Commissioners. Very few consumptives will voluntarily enter a workhouse infirmary. The medical officer of health has now been unofficially informed that if the borough council makes an application to the London County Council to have the hospital in the Kennington Park-road taken over for the reception of the cases of tuberculosis above referred to, the London County Council will be prepared to bear all the maintenance charges. The acquiring of this hospital would not prevent the Council recommending legislation giving powers for the compulsory

removal of dangerous infectious cases of tuberculosis from their homes to an institution. This question is dealt with in the second part of the report, which points out that compulsory powers of removal by local authorities in respect of certain cases of infectious disease already exist under the Public Health (London) Act, 1891, but that this does not extend to tuberculosis.

"Article 7 of the Tuberculosis (in hospital) Regulations, 1911, provides that nothing in the Regulation shall authorise or require a medical officer of health or a local authority to put in force any enactment which renders a consumptive or the person in charge of the patient or any other persons liable to a penalty, or subjects the person to any restriction, prohibition or disability affecting himself or his employment, occupation or means of livelihood on the ground of his suffering from tuberculosis.

Compulsory powers of removal have, however, been obtained by some of the provincial councils under private Acts of Parliament—e.g., the St. Helens Corporation Act of 1903.

The Public Health (Prevention and Treatment of Disease) Act, 1913, also contains a special clause dealing with treatment of tuberculosis. Sec. 3 empowers any sanitary authority to make any such arrangement as may be sanctioned by the Local Government for the treatment of tuberculosis; this power to be in addition to and not in derogation of any other power."

If this section be acted upon it may become the practice of one borough compulsorily to remove advanced consumptives, whilst another might adopt less drastic means. Having regard to the fact that a certain percentage of consumptive cases are a danger and cause of infection to others, and refuse to enter an institution or take steps to prevent the spread of the disease, compulsory removal should be general throughout the country in certain cases. The Tuberculosis Regulations of 1911 should be extended so as to give the medical officer of health power to order, with due legal precautions, the compulsory removal of a case where it is clearly proved that such a case is tending to spread the disease and the affected person refuses to take advantage of voluntary measures offered.

#### *The Hairmyres Colony.*

The *British Journal of Tuberculosis* for July makes Mr. J. E. Chapman's memorandum on "Colonies" (L. G. B. Reports on Public Health Subjects. New Series. No. 122) the occasion for a long and useful review of the place of such colonies in the anti-tuberculosis campaign. An interesting experiment was confirmed on June 14th when the Hairmyres Colony was officially opened by the Secretary for Scotland. As long ago as 1905 the district committee of the Middle Ward of Lanarkshire made a beginning in the systematic treatment of pulmonary tuberculosis under a system of voluntary notification. Since that time their hands have been greatly strengthened by the coming of compulsory notification and the provisions in the Insurance Act for the treatment of tuberculosis. Experience has shown them that the method of treating consumptives for three months in a sanatorium and then allowing their patients to compete for a livelihood in the open market of labour was satisfactory neither from the clinical point of view nor from that of the local authority which was constantly called upon to provide treatment for cases of relapse. The colony will be peopled by children as well as by selected cases of adults in whom the disease has been arrested by sanatorium treatment. The former will be taught in open-air schools, and the latter trained, under medical supervision, in various outdoor industries, such as market-gardening, bee-keeping, poultry-farming, and forestry.

#### *A Colony Scheme for the East Midlands.*

The Mayor of Nottingham with Major Brockington, of Leicester, recently presented a tuberculosis colony scheme to the Minister of Pensions on behalf of the East Midlands Joint Committee. The site chosen by the committee for the establishment of a training colony is at Bretby Hall, near Burton-on-Trent. The Derby borough committee, which is at present dealing with a large number of applications from consumptives, has passed a resolution strongly urging the Government to give effect to the scheme.

#### *Anti-tuberculosis Campaign in Bombay.*

The annual report of the King George V. Anti-Tuberculosis League shows an increase in the amount of treatment provided, the patients treated being 1215, as compared with 972 in 1917. On Dec. 7th, 1918, Lord and Lady Willingdon opened a sanatorium, which has been erected by the league from voluntary subscriptions. Up to the end of last year treatment was given for the most part in the two dispensaries, in which, since 1913, more than 4000 cases have received treatment. About three-quarters of these cases had

tuberculosis of the lungs and the remainder were chiefly cases of tuberculous glands. Domiciliary treatment has also been supplied by the doctors and nurses, and the occasion made use of for much valuable propaganda. This part of its work is rightly regarded by the officers of the league as very important, since consumption spreads to a great extent among the uneducated natives who have no conception of its infectivity. For the enlightenment of these classes lectures are arranged in the different native languages and pamphlets are distributed describing the early signs of consumption, and giving instructions for its treatment in the home. A systematic examination of school children has convinced the medical officers that early tubercle can often be diagnosed by loss of weight.

#### *The American Tuberculosis Association.*

At the annual meeting of this association held recently in Atlantic City Sir William Osler was elected a vice-president. A resolution was adopted, viewing with grave concern the efforts being made in certain quarters to have the Daylight Saving Bill repealed, and protesting against any attempts to impede the operation of such law. The great help it was at the present time in preserving the health of the country generally was emphasised. The Army medical officers present discussed the responsibility of the Government for the proper care and treatment of the tuberculous soldier prior to his return to civilian life. A representative from Surgeon-General Estes Nichols's office (of No. 16 General Hospital) then described a plan which was under consideration. It was proposed, he stated, to give treatment in special reconstruction towns or communities, which would be located upon lands in the National forests, the idea being to attract the patients to healthful wood-working industries, and to afford them an opportunity to retain control of the land holdings after they were cured. They would be under proper medical supervision, but not to the same extent, of course, as during their time in a sanatorium. Such communities would require financial assistance at first, but eventually should become self-supporting.

#### *The Hog as a Test for Bovine Tubercle.*

Dr. Burton Rogers, of Chicago, Illinois, has recently drawn attention to the value of the hog as an indicator of the existence of bovine tuberculosis on a farm. Wherever pigs and cows are kept together it is found that the former greedily devour the faeces of the latter; indeed, the symbiosis is often purposely arranged in order that cowsheds may be kept clean. The tuberculous cows swallow their sputum, and the bacilli thus pass out in their faeces, with the result that the pigs become infected. Among 40 million hogs examined by American veterinary inspectors in 1917 3,974,000, or nearly 10 per cent., were found to be tuberculous. Dr. Rogers points out that if the pigs slaughtered and subsequently examined had been previously labelled with the name of the farm on which they were reared, valuable presumptive evidence of the existence of bovine tubercle and of its localisation to specific farms would have been obtained and could have been used with great advantage in a campaign to eradicate the disease from among cattle.

## NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

#### *An Indian Ministry of Health.*

THE conference of provincial medical and sanitary officers recently summoned by the Government of India has concluded its meetings at Simla under the presidency of Sir San Karan Nair, member of the Viceroy's Council for Education and Sanitation, who invited his hearers to consider how a central health organisation could coördinate the work of preventive action, clinical practice, and medical research. As regards the question of assistance to the provinces in severe epidemics, he made the suggestion of a mobile corps, lent in normal times to the provinces to supplement the provincial staffs, but subject to the withdrawal by the Government of India acting on the advice of its Public Health Board, in order to concentrate in any area where extensive epidemic disease had broken out. The function of the corps would include popular education in preventive methods. A resolution was passed calling for the establishment of a Central Public Health Board consisting

of official and non-official members, and the creation of similar boards in the provinces. The conference laid stress on the importance of certain kindred measures such as the establishment of an epidemiological statistical bureau, the increase of curative medical staffs, the multiplication of dispensaries, and the future development of research facilities on the lines of the Central Research Institute.

#### *Lahore Milk-supply.*

In the course of the campaign which he has inaugurated against food adulteration the officer commanding the Lahore area, now under martial law, has come across some surprising figures in regard to the milk-supply. Of large numbers of samples that have been analysed only two have been found absolutely pure, the extent of adulteration varying from 2 to 34 per cent., with a general average of not less than 10 per cent. About 2000 maunds of milk per diem are consumed in the Punjab capital, which would mean that 200 maunds of water are being daily sold as milk. As the price of milk is 3 annas per seer, or Rs.7·8 per maund, the Lahore public are daily being robbed of Rs.1500, or, say, Rs.5½ lakhs, per annum. Heavy fines and sentences of imprisonment under martial law have for the moment practically stamped out the practice of adulteration, with the rather amazing result that, the available number of cows remaining the same, there is a distinct shortage of milk.

#### *The Red Cross in India.*

The Indian Joint War Committee of the Order of St. John of Jerusalem and the British Red Cross Society have just issued their report on last year's activities. The figures of expenditure in the various centres in which Indian Expeditionary Forces were engaged and in India itself speak eloquently of the extent of its operations. The total expenditure during the year was 51½ lakhs of rupees (£300,000 sterling); 37½ lakhs were expended on account of Mesopotamia, over 1½ on East Africa, Egypt, and Palestine, and the remainder was made up by expenditure on the Marri and Waziristan operation and on hospitals in India itself. The expenses of management amount only to 63 per cent. (or just over 3 pies in the rupee) of the total expenditure. The history of the year shows great progress in the assumption by Government of responsibility for this type of expenditure. The standard supply of Government equipment to military hospitals and field medical units has been greatly extended, and numerous articles originally classed as "comforts" are now recognised as "necessaries." The burden, which will in the future fall on Red Cross activities, will thus be materially lightened.—The Baluchistan Red Cross and Comforts Fund has undertaken to supply the whole of the troops in the East Persian Cordon and on the lines of communication with regular consignments of tobacco and other amenities, which are sent to each unit in rotation.

#### *The Health of the Army in India.*

The annual report of the Sanitary Commissioner with the Government of India has just been published. The figures presented compare favourably with those of the two preceding years; for 1917 the death-rate was 4·83 per 1000, as against 6·54 in 1916, 5·95 in 1915, and 4·51 the ratio for the pre-war quinquennium, while the admission ratio is stated at 771·7 per 1000, comparing with 772 in 1916, 823·1 in 1915, and 567·2 in the quinquennium before the war. There was a substantial increase, however, in the ratio of constantly sick, even when comparison is made with the two preceding years, the figures for 1917 being 45·66 per 1000, while the ratio was 39·75 in 1916 and 39·08 in 1915. This difference, we are told, is "accounted for chiefly by the increased number of admissions for two diseases which require prolonged treatment—namely, venereal disease and malaria—of which diseases the average constantly sick ratio has increased 5·33 per 1000." The ratio of men sent home invalided was considerably smaller than in the two preceding years, though very much greater than in the pre-war period. Malaria was again the great cause of sickness and inefficiency among the British troops in India. The mortality rate among the Indian troops showed a marked increase, the figure being 11·51 per 1000 as compared with 8·97 in 1916 and 8·55 in 1915. An increase in venereal disease was also experienced among the India troops, the chief factor in which is reported to have been the large number of young recruits constantly joining stations and replacing the trained men going on active service.

## Correspondence.

"Audi alteram partem."

### A CRITICISM OF

### THE MEMORANDUM ON MALARIA.

To the Editor of THE LANCET.

SIR,—You published in THE LANCET of July 12th a note upon the Memorandum on Malaria, recently issued by the Ministry of Pensions, and purporting to assist the practitioner in dealing with malaria and, in particular, with the diagnosis, treatment, and prevention of this disease. Bearing the name of Sir Ronald Ross, this Memorandum is certain to receive considerable attention, and to a smaller circle the name of his collaborator, Lieutenant-Colonel S. P. James, will be equally well known.

Perusal of this Memorandum shows that it is written by those who have but little knowledge of the circumstances of general practice and leads one to suppose that adherence to its precepts would be of grave disadvantage to our patients, particularly pensioners, and ourselves. There is also a wider point of view. This is an official Memorandum, and may be presumed to carry on the army policy of occasional issue of memoranda on diseases of immediate importance. The policy was admirable, but the actual memoranda were often of dubious value. One might well have hoped that the Pensions Ministry would have sought to improve on this. It has not done so. If the criticisms I make are sustained there can be no doubt that the pamphlet ought to be superseded forthwith.

#### *Criticisms and Reasons.*

I make the following criticisms, for each of which I adduce reasons, viz. :—

(1) That the description of malaria given is not that of the form of malaria which will give us most trouble in the British Isles, and is, moreover, calculated rather to obscure than to elucidate the nature of the disease.

(2) That the methods of diagnosis on which most emphasis is laid are of little or no value to the practitioner in the British Isles, and that important methods of diagnosis have been omitted.

(3) That the treatment suggested is not adapted to the class of case to be treated, is in part dangerous, and errs gravely in emphasising the value of quinine and excluding other factors necessary for recovery.

#### *1. Description of Malaria.*

The reasons for my first criticism are as follows. The description of malaria as a morbid process takes up most of the paragraphs headed "The Diagnosis of Malaria." It is almost wholly devoted to the nature and periodicity of acute attacks of fever. Particular emphasis is laid on periodicity. Only in the rarest cases is the general practitioner likely to be able to keep or obtain any accurate record of his patient's temperature. These paragraphs are therefore almost useless. The description of a rigor is, of course, accurate enough, but the general practitioner, faced with a definite rigor in a patient returned from abroad, and probably volunteering the information that he has an attack of ague, has no need to read up the symptoms of malarial rigor. The symptoms of the apyrexial stage are hardly mentioned, and the disease is dealt with as if it consisted of a sequence of rigors with an absolutely inactive infection between times. This is scientifically incorrect and misleading, and clinically very fallacious. However, it is admitted that a succession of rigors may give rise to certain signs, &c. These are described under the heading "Malarial Cachexia." I quote, "Considerable enlargement of the spleen and severe anæmia are the obvious clinical physical signs." "Serious symptoms are usually absent unless the patient is suffering from another disease." "Chronic irregular 'low' fever is not present." "As a rule, patients suffering from this condition are not emaciated." One can only remark that if such a condition as considerable splenic enlargement and severe anæmia without serious symptoms or fever or emaciation does actually exist, I never had the fortune to see it in one of Sir Ronald Ross's own hospitals. It may occur in the tropics, but it does not at home. My experience in two special malaria hospitals strongly suggests that this sort of clinical

picture-making is inaccurate and misleading when addressed to practitioners in the British Isles, and is therefore wholly out of place in the Memorandum. There is also a list of "the chief 'pernicious' symptoms sometimes met with in cases of acute malarial fever." These are useful in their place, but they are not nearly so useful as would have been some account of the symptoms as we shall see them and as they have actually been seen in the hospitals over which Sir Ronald Ross held sway. I would instance chronic tachycardia and "effort syndrome," chronic headache and depression, chronic pains in the side, &c. I have dealt with these elsewhere.<sup>1</sup> My subsequent experience has shown me that I was right in supposing that it was such symptoms as these that were going to be the despair of medical referees, medical boards, and practitioners, whereas those of the acute attack presented no difficulty. I should like further to state that these symptoms were studied only with the strongest official discouragement, even to the extent of refusal of permission to publish any paper on them. That this should be so makes one doubly anxious to raise discussion on the deductions of Sir Ronald Ross and others from the same material, for the two different views we have of the disease as seen at home are scarcely compatible, and it is well that truth should prevail.

### 2. Methods of Diagnosis.

My second point is that the methods of diagnosis on which most emphasis is laid are of little or no value to the practitioner in the British Isles. These methods are three. The first is entitled "Clinical Symptoms and Signs." The only one mentioned is periodic fever. This is the one sign of which the practitioner can hardly hope to get accurate record. The second is "The Results of Blood Examination." No mention is made of what results are to be expected, presumably nothing but the presence of the parasite suffices. Yet there are other important points in the blood examination—e.g., pigment cells; and even if the practitioner were presumed to be too busy to examine his own blood slides, he might at least be put in a position to understand a specialist report on the same. The third point is "The Effects of Therapeutic Doses of Quinine." We may sometimes be driven to this resort, and it is one to bear well in mind, but it is not the kind of method which much enhances one's reputation among patients, and it is absolutely useless unless fever be actually present. Most of the pensioners who have come to me for advice had to be diagnosed by means other than any of these three, and so also will they have to be diagnosed and their pensions assessed by medical boards and referees. No other method of diagnosis is mentioned. Might not the hyperalgesic areas described by Carmalt Jones have been just mentioned? Is not herpes labialis important confirmatory evidence where a recent attack is alleged, or perisplenitis, or slight jaundice? I feel fully justified in the statement that the methods of diagnosis laid down are of little use to practitioners, while those omitted would have been of great assistance.

### 3. Treatment Suggested.

My third point is that the treatment suggested is not adapted to the class of case to be treated, is in part dangerous, and errs gravely in emphasising the value of quinine and excluding other factors necessary for recovery. The treatment advocated is quinine and nothing else. This is to be given for *three months* after each acute attack. I have seen a great many patients from Sir Ronald Ross's hospitals, and never did I meet one who could suggest he was cured by any method of giving quinine. Some had had heroic doses, some had had none. One of the latter was cured, many of the former were certainly not. This is a vexed question, but I would ask fellow-practitioners dealing with malaria, which is being overcome by the natural resistance of the body in this country, not to follow methods which may be suitable for those who are liable to frequent reinfection—a distinction between cases which Sir Ronald Ross does not seem to make or to consider to have any bearing on treatment. The treatment I brand as dangerous is that by the intramuscular route. The instructions are "..... the operation presents no difficulty. The stab should be made deeply into the gluteal muscle and the solution injected." The result of such instructions, or lack of more definite instructions, resulted in so many paralysed

limbs that I was informed by an officer on a hospital ship that each boat was bringing home four or five cases. Certainly there followed stringent orders that intramuscular quinine must only be given under the supervision of the officer in charge of a medical division. Moreover, Colonel Leonard Dudgeon has recently most ably demonstrated the destructive results of intramuscular injections. Are we to learn our lessons so badly that this method is still to be advocated with all the weight of Sir Ronald Ross's name and the approval of a Government department? We may well say, "Pity the poor pensioner." Finally, I desire to draw attention to the total lack of any mention of the general hygienic treatment of malaria as carried out in convalescent camps and of the peculiar measures adapted to the successful treatment of such otherwise fatal complications as blackwater fever, and, generally speaking, the "pernicious" symptoms referred to in the Memorandum.

### The Author's Views.

I fully recognise the fact that I am pitting the opinions of an unknown individual against those of an acknowledged authority. But the practical results of this authority and a genuine interest in the welfare of pensioners compels me to the opinion that it is high time someone spoke up. I would state my own views on the diagnosis and treatment of malaria as follows:—

1. The diagnosis of malaria as seen between actual attacks in this country can only be made by careful investigation of all the symptoms, including particularly those mentioned in the paper referred to, and only by such careful attention can any proper estimate of the degree of disablement be made.

2. The most important principle in the treatment of malaria in pensioners is the improvement of the natural resistance of the body with the aid of as little quinine as possible.

I am, Sir, yours faithfully,

GORDON WARD, M.D. Lond.

Sevenoaks, Kent, July 14th, 1919.

## TRAINING OF THE JUNIOR OFFICERS OF THE INDIAN MEDICAL SERVICE IN INDIA.

### To the Editor of THE LANCET.

SIR,—The enclosed letter, addressed to the Secretary of State for India, if published in THE LANCET, should arouse professional interest in a very important question.

I am, Sir, yours faithfully,

G. J. H. EVATT, M.D.,

Major-General (retd.).

July 10th, 1919.

### [ENCLOSURE.]

From Major-General Sir George J. H. Evatt, K.C.B., M.D.,

Junior United Service Club, London, S.W. 1.

To the Right Hon. the Secretary of State for India,

India Office, London.

July 10th, 1919.

SIR,—I have the honour to submit the following proposals as to further training in India of the young officers of the Indian Medical Service before appointment to any medical post in India.

- (2) All newly appointed medical officers to be detained at Bombay on arrival for six weeks and to be constituted in a "class" to study Health Conditions and Sanitary Arrangements in and about Bombay city and neighbourhood.

- (3) Representative officials of local experience to show and explain to the class of young officers:—

- (a) The system of Drainage of Bombay city.
- (b) The Sewerage system of Bombay city and district.
- (c) The Water-supply system as to collection, storage, and distribution.

- (d) Public Baths and Wash-houses.

- (e) Segregation of Infectious and Contagious Diseases, arrangements for prevention and treatment of Cholera, Small-pox, Plague, Malaria. Segregation hospitals. Vaccination in full. Leprosy to be studied in full.

- (f) Hospitals in Bombay to be visited as to structure. Training of nurses. Convalescent establishments attached to hospitals. The cost and expenditure of hospitals and the means of raising funds explained.

- (g) Lunacy and Lunatic Asylums to be fully visited and explained to the young officers in a class by efficient specialist officer.

- (h) The Races of the Indian People to be explained by a skilled specialist in this racial subject.

- (j) The Creeds and Castes of the Indian People to be popularly explained to the young officers.

- (k) Outline description of the Indian Empire, its Presidencies, Native states. Provinces, and description of Government methods. The Province and the District.

<sup>1</sup> Proc. Roy. Soc. Med., 1919, xii., Section of Medicine, pp. 15-36.

(l) The Methods of dealing with prisoners under confinement in jails throughout the country. Jails to be visited and explained to the young officers very fully.

(m) The Cantonment of Poona to be visited, studied, and explained by competent local officers. Barracks and hospitals to be seen.

(n) The class to be controlled by the Director of Medical Services, Bombay, who would nominate instructors and maintain discipline during the course.

(o) Detention Allowance to be granted to the young officers. A medical officer not under the rank of Major to be attached to the class pro tem. as Discipline Officer and Director of Studies and Chief Instructor. Two officers as assistant instructors could be allowed.

(p) An Examination might be held at the termination of the class to see what progress has been made.

(q) Certain public men who would represent sections of the Indian people to be invited to address these young officers during the course of study.

I should be glad to have an acknowledgment of this letter.

Your obedient servant,

London, 1919.

G. J. H. EVATT, M.G.

## INDUSTRIAL MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—Dr. Prosser White's letter in THE LANCET of July 5th emphasises two of the most important duties of a real factory doctor—i.e., close familiarity with actual working conditions and the necessary investigation of all cases of injury. To familiarise himself properly with the conditions of employment and with the reactions of the workers to their work the doctor should practically live and work amongst his workers. Periodical inspection by a trained observer can, perhaps, do much, but even in his case several days spent in the factory would throw light on much that passes unnoticed or appears obscure on a cursory inspection and would familiarise him with the local difficulties which his full-time colleague appreciates so thoroughly. For the purpose of prevention of accident and disease the constant supervision of the factory M.O. and of his "tentacles"—i.e., the foremen, works managers, &c., who work with him to the common end of good output, health, and content of workers—is far more valuable to both workers and management than occasional visits by headquarters staff and by the C.F.S. when, and not till when, some trouble has occurred. Moreover, the full-time man will have examined every worker and carded his findings for reference. This index will serve as evidence in case of a claim for compensation under the Workmen's Compensation Act.

*The Industrial "Expert."*

In the second of your special articles on an industrial medical service you suggest that it is for the Certifying Surgeons' Association to organise proper training schemes for the training of the industrial specialist. But in so doing the interests of the full-time medical officer and that of the lay workers in the factory should be studiously borne in mind. In practice full-time medical officers handle many things which at first sight do not appear strictly within the duties of a medical man, such as absenteeism and its prevention, causes of wastage of factory personnel, the administration of the Workmen's Compensation Act, canteen supervision, and the investigation of many grievances of workmen (since there is very often a medical side to such).

I can scarcely consider the quarterly inspection of workers as adequate to detect hygienic faults. Nor is it satisfactory to leave the working out of the remedies to an "expert" from headquarters, invaluable though his advice may be in its proper place. The full-time medical officer is also in a better position to get faults remedied than the headquarters man, since he can continue worrying the management until the fault is remedied.

*The Factory Doctor and Private Practice.*

It is doubtful how much private practice a factory doctor should undertake. On the one hand, he should be in touch with the modern developments of medicine, but on the other it is his duty to treat the factory rather than the individual worker, which means that his function is preventive rather than curative so far as the individual is concerned. The workman's panel doctor is the man to represent the private interests of the individual. Moreover, the man has a legal right to free choice of doctor, and an attempt to force him to choose the factory doctor is scarcely to be desired in a

civilian community. Cases will arise in which the apparent interest of the factory runs counter to that of the man, as when tuberculosis or venereal disease is in question. How, then, can a doctor serve both masters fairly and please both? He will also run the risk of losing practice if he does not please the worker and his wife by his decisions.

*Supply and Demand.*

It is true enough, as stated in the article, that supply creates demand; and here trained factory doctors are the supply. But demand should be stimulated simultaneously, and that was why I wrote to the *Times* and *Cassier's Monthly* rather than in the first instance to medical papers. The daily press has avoided such subjects till lately, perhaps fearing that the political aspect of attempts to benefit the condition of workers might do them harm. Managers in the past have regarded the doctor askance, since it is through his certificates that they have lost labour. Some of them are beginning to see that had the doctor been in charge, they might have at least lost less labour, since he would probably have sent the worker off duty sooner, and so prevented a prolonged illness. Moreover, the full-time man is far more in a position to judge whether the disease or injury was in fact due to factory conditions than an outsider, since he should have at his disposal the records of work done by each worker on any day, as well as legal evidence, with witnesses' names, in case of accident, besides a more intimate knowledge of the factory conditions and of any peculiarities in the way of special poisonings or disorders due to special processes used in the factory. The value of a full-time doctor previously trained in factory medicine and law, as well as in the other accessory subjects needed by a factory doctor, will be evident to an enlightened manager, and such a doctor will stand a better chance of getting a good appointment. It is of no use to supply these men without some sort of guarantee that they will get suitably paid jobs. If we would raise the demand for trained factory doctors, we should address the managers in terms of output, the workers in those of wages, and the general public in those of industrial peace and health. The three things are synonymous, but the form in which they appeal to the different classes concerned varies, and should be considered in our appeals. The type of man to train as a factory doctor is the enthusiast with the doggedness of the "importunate widow." He should have had some training in research methods, and should be a good physiologist and psychologist, knowing something of mass-psychology.

I am, Sir, yours faithfully,

July 5th, 1919.

H. GEORGE P. CASTELLAIN.

## EPIDEMIC PERINEPHRIC SUPPURATION.

To the Editor of THE LANCET.

SIR,—The recent letters in THE LANCET on the above subject must have been of great interest to a large number of medical officers who have served abroad during the last few years. In Macedonia there were many cases: the diagnosis was complicated by the prevalence of large and tender livers and spleens. Lieutenant-Colonel J. Patrick and the writer collected the notes of some 20 cases last year, and this number falls far short of the total that occurred in the Force. As regards bacteriology, *Staphylococcus aureus* is undoubtedly the usual organism present in the pus. In one case Captain R. R. Elworthy isolated a *Staphylococcus albus* and this was confirmed by Colonel Leonard Dudgeon. Dr. W. Pasteur may be interested to hear that I know of five cases who died of staphylococcal pyæmia. In at least one of these *Staphylococcus aureus* was isolated by blood culture. As regards his statement that "the urine never contained pus," pus, in quantities varying from a trace to a considerable quantity, was present in half our cases. Albumin was present in rather more than half, and *Staphylococcus aureus* was isolated from the urine in rather less than half the cases.

Radiographic examination was helpful in some cases, the usual signs being a haziness on the affected side with loss of definition of the kidney shadow and of the shadow thrown by the psoas and quadratus lumborum. Diminution of the movement of the diaphragm on the affected side was also noted in some, with absence of elevation of the dome at a point which helped to differentiate a right perinephric

abscess from a hepatic abscess. The vertebral shadows were normal. All the cases referred to occurred before the influenza scourge reached the Balkans. I have no reason to think that influenza affected the incidence of the perinephric infection, though I have heard of cases in which this abscess occurred in patients suffering from influenza and pneumonia.

I am, Sir, yours faithfully,

H. A. T. FAIRBANK,

Major, R.A.M.C. (F.F.), late Lieutenant-Colonel; Assistant Consulting Surgeon, B.S.F.

Harley-street, W., July 9th, 1919.

## THE POSITION OF NATIONAL STATISTICS.

To the Editor of THE LANCET.

SIR,—It is a matter of common knowledge to all who have had occasion to use official statistics, whether published or departmental, that the national and imperial equipment for obtaining and publishing statistical data is very imperfect in its scope and inadequate in its machinery. Further, the efforts made are departmental, are under no common controlling or directing authority, and suffer very gravely from lack of coördination. There is no need to adduce proofs of these statements nor to enumerate the various efforts, fruitless in the main, which have hitherto been made to remedy these defects.

The Council of the Royal Statistical Society have appointed a special committee to deal with the subject in the belief that the time is now ripe for a new movement in the direction of reform and that the consciousness of the existing defects is present to the minds of His Majesty's Ministers, Members of Parliament, and civil servants, as well as to others interested in statistics. It is proposed to petition His Majesty's Government to set up a Parliamentary Committee to examine the whole question of the collection and presentation of public statistics, and to report on means of improvement. It is believed that this method of procedure is more likely to be effective than the pressing of specific proposals on His Majesty's Ministers. The officers of local governing and other public bodies, as well as of scientific societies, are being invited to bring the matter at once before their councils. Moreover, publicists and others who are known to be interested, are being approached directly.

We ask the courtesy of your columns to lend support to this movement, and invite your readers to help with their influence and signatures. The Council will be glad if all who are disposed to sign such a petition would communicate with the Secretary, Official Statistics Committee, Royal Statistical Society, 9, Adelphi-terrace, W.C.2. A copy of the petition will then in due course be sent to them for signature.

I am, Sir, yours faithfully,

GEOFFREY DRAGE,

Chairman, Official Statistics Committee.

July 10th, 1919.

## HUTCHINSON'S TEETH.

To the Editor of THE LANCET.

SIR,—The point raised by Dr. David Walsh in a letter in your issue of July 12th has been dealt with by two masters of the craft. Sir Jonathan Hutchinson,<sup>1</sup> in an original communication to the Pathological Society, made the following statement:—

"The recognition of the subjects of inherited syphilis, by means of their incisor teeth, can only be effected, with any confidence, between the ages of 8 and from 25 to 30. Later than 31 the notches have generally been worn level, and the teeth merely resemble those of a much older person. I have seen teeth preserving their peculiar syphilitic stamp in patients of middle age, but in a large majority of instances such is not the fact."

Professor A. Fournier,<sup>2</sup> in his lectures on the subject, states—the translation is a literal one:

"A second point, and one of real practical interest: the Hutchinson tooth modifies itself in form beyond the age of adolescence and finishes by losing absolutely its characteristic notch. Under the influence of functional use the arch of the free border diminishes progressively in height, and the mathematical rise is lowered. It might be described as an arch which is falling in. There comes a time when the curve of the arch is scarcely perceptible. The arch appears to have straightened itself out. Finally, all trace of the notch disappears, and the free border transforms itself into a nearly straight line. To be precise, from the age of 20 to 22 years, the notch is markedly lessened,

at 25 it is almost straight. At this period there still exists, for a certain time at least, a certain sign which allows us to recognise a lesion, it is the bevel of the anterior border of the notch. Remember that the Hutchinson notch is cut away from above downwards, and from before backwards at the expense of the anterior border. This bevel, which caps and dominates the notch, is naturally only affected in the later stages, by the rubbing away of the tooth, therefore it persists, and is quite easily recognisable, at a period when the notch has disappeared. It constitutes, therefore, the last trace of the lesion. After the age of 25 years the bevel in its turn becomes effaced ..... this fact is so well known that it has been very truly stated that after the thirtieth year the Hutchinson tooth no longer exists."

To illustrate his lecture Fournier showed a case which must have very closely resembled the case described by Dr. Walsh.

I am, Sir, yours faithfully,

G. D. KETTLEWELL.

V.D. Clinic, South Devon and East Cornwall Hospital,  
Plymouth, July 12th, 1919.

## Obituary.

FREDERICK PAGE, M.D. EDIN., F.R.C.S. ENG.,  
D.C.L. DURH.,

EMERITUS PROFESSOR OF SURGERY IN THE UNIVERSITY OF DURHAM.

Professor F. Page died at his residence, 20, Victoria-square, Newcastle-on-Tyne, on July 3rd, at the age of 79 years. He was the son of a well-known surgeon in Portsmouth, and after a private school education entered Edinburgh University, where he graduated M.D. in 1868, becoming house physician at the infirmary, and then enlarging his range of vision by a trip to Western Australia, where he held a position at the Colonial Hospital, Perth. Four years on the junior staff of the Royal Infirmary, Newcastle-on-Tyne, determined his stay in the city with which his professional and public activities were thereafter identified. As a surgeon his reputation soon extended beyond the Royal Infirmary and the Fleming Memorial Hospital for Sick Children, where his attendance was assiduous. He became professor of surgery in the University of Durham and registrar of the College of Medicine, receiving in 1888 the degree of M.A. (hon. causâ), and examining in clinical surgery at his old University of Edinburgh. To a number of special hospitals he was also attached in a consulting capacity. To most men these onerous duties would have afforded sufficient outlet for their powers, but Page contrived to reconcile a life of public service with his many professional engagements. He was on the Commission of the Peace, becoming chairman of the visiting committee of prison justices and presided over the licensing committee for the city. In private life his tastes were literary and dramatic.

Professor Page married in 1876 the eldest daughter of Mr. John Graham and niece of Professor T. Graham, F.R.S., sometime Master of the Mint, by whom he had a son and two daughters.

SIR J. H. MEIRING BECK.

THE death of Senator Sir J. H. Meiring Beck, M.R.C.P., F.R.S.E., Minister of Posts and Telegraphs in General Louis Botha's Cabinet, is a great loss to the Union of South Africa. Sir Meiring Beck was a true South African, and his chief aim during his political life was to heal racial estrangements and mollify party asperities. While a loyal adherent of General Botha, he was popular with all political parties. He combined, in fact, in no small degree the best attributes of a cultured English gentleman with the fervour of the Afrikaner patriot. Born at Worcester, Cape Province, in 1856, he was educated at the South African College, Cape Town, and afterwards studied medicine in Edinburgh, Berlin, and Vienna. At Edinburgh he graduated with first-class honours, gaining the Beaver Scholarship. He practised at Kimberley, Worcester, and Rondebosch, becoming President of the Colonial Medical Council and President of the British Medical Association, Cape Town. For over 20 years he was a member of the Cape University Council.

Sir Meiring Beck represented his native town of Worcester in the Cape Parliament, was a Cape delegate at the National Convention of 1908-9, and on the creation of the Union was made a Senator. After filling the post of chairman of committees in the Senate he became Minister of Posts and Telegraphs in 1916.

## Medical News.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—A quarterly meeting of the Council was held on July 10th, Sir George H. Makins, the President, being in the chair.—The President reported the result of the recent meeting of Fellows for the election of two members of Council as given in THE LANCET of July 12th, and Sir Berkeley Moynihan and Sir Cuthbert Wallace were introduced and made declarations in the terms of the oath prescribed by the Charter of 1800 and took their seats as members of the Council.—It was resolved to grant, in conjunction with the Royal College of Physicians of London, Diplomas in Public Health to 12 successful candidates (11 men and one woman).—The recent resolution of the General Medical Council that every student should be required in future to attend a practical course in ophthalmology was considered, and it was resolved to refer it to the Committee of Management for consideration.—A letter was read from the secretary of the Joint Matriculation Board of the Universities of Manchester, Liverpool, Sheffield, and Birmingham, inquiring if the College would accept the school certificate issued by the Board for the purpose of the exemption of the holder of such a certificate from the Preliminary examination. The matter was referred to the Committee of Management.—A letter was read from Dr. F. Wood Jones resigning his appointment as Examiner in Anatomy under the Conjoint Examining Board in consequence of his having been appointed to the chair of anatomy in the University of Adelaide.—It was resolved that Dr. Wood Jones's resignation should be accepted and should take effect on his departure from England in the autumn. It was further resolved that he should be permitted to deliver his Arris and Gale lecture in October next.—The President reported his attendance at meetings of the panel to assist the Minister of Health in the formation of a Consultative Medical Council. A letter was read from Dr. Christopher Addison, stating that, with the advice of the temporary panel constituted in accordance with the terms of his letter of May 27th last, he had framed the list of bodies to be invited to suggest the names of persons suitable to become members of the Consultative Council on Medical and Allied Services to be set up in England under the Ministry of Health Act, 1919, and asking the Royal College of Surgeons of England to furnish him with the names of six persons who, in its opinion, would be specially suitable, if appointed by him, to serve upon the Council as first constituted; pointing out that, while it is desirable that the Minister should, before coming to his decision, have as large a range as practicable of persons willing and suitable to serve only a relatively small proportion of the persons whose names are suggested can in the first instance find a place upon the Council, the total membership of which might with advantage be kept below the maximum number of 20 contemplated by the Order; and stating that the Act provides for the payment to members of the Council of a subsistence allowance and reasonable compensation for loss of remunerative time and for the repayment of travelling expenses. The matter was referred to a committee to consider and report.—Sir George Makins was re-elected President, and Sir Anthony A. Bowly and Sir John Bland-Sutton were elected Vice-presidents. Sir D'Arcy Power was re-elected a member of the Executive Committee of the Imperial Cancer Research Fund.—The next meeting of the Council will be held on Thursday, July 24th.

**UNIVERSITY OF BRISTOL.**—The following professorial appointments have been made:—Chair of Education: Helen Marion Wodehouse, M.A., D.Phil., Principal of the Bingley Training College, Yorkshire; Henry Overton Wills Chair of Physics: Arthur Mannering Tyndall, D.Sc., Acting Head of the Department of Physics in the University during the war; Henry Overton Wills Chair of Physiology: George A. Buckmaster, M.A., M.D., D.P.H., Assistant Professor of Physiology in the University of London.

At examinations held recently the following candidates were successful:—

### DEGREES OF M.B., CH.B.

*Final Examination, Part I, only (including Forensic Medicine and Toxicology).*—Hilda Mary Brown.

*Second Examination, Part II, (completing examination).*—Macdonald Critchley, John Rukin Duerden, and Phyllis Thekla Slepmann.

### DIPLOMA IN DENTAL SURGERY.

*Final Examination.*—Violette Burgeois.

*Third Examination.*—Edward Jaue, Tusker.

*Second Examination.*—Norman Harry Bodenham and Kenneth George Hyland.

### DIPLOMA IN PUBLIC HEALTH.

Alison Edgar Wilson.

**UNIVERSITY OF MANCHESTER.**—The following have obtained the Diploma in Public Health of the University:—

A. W. Baker, G. H. T. N. Clarke, C. J. Crawford, C. O. Hargreaves, A. Heath, J. L. Meynell, E. N. Ramsbottom, H. F. Sheldon, and E. H. Walker.

**ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, AND ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.**—The following candidates have passed the Triple Qualification Examinations:—

### FINAL EXAMINATION.

John Stewart Marshall Connell, Robert Berry Forgan, Poon Lip Loh, Thomas Lloyd Edwards, John Kohler Steel, John Fraser Kerr, Ssem Stein, Thomas Richard O'Keefe, William Gibb, Daniel Adrian Stegman, Maurice Julius Woodberg, and Jung Babadur Singh.

*Medicine.*—Norman Joseph Patterson, Mandayam Anandampillay Parthasarathy Iyengar, Gordon Beveridge, Thomas Dier, Lewis Rifkind, John Alfred Alexander Duncan, and John Richard Larson.

*Surgery.*—Thomas Dier, Thomas Ferguson Minford, and Thomas Blaney.

*Midwifery.*—Norman Joseph Patterson, Mandayam Anandampillay Parthasarathy Iyengar, Gordon Beveridge, Lewis Rifkind, Patabandi Martin Fernando, James Innes Coventry, John Alfred Alexander Duncan, and John Richard Larson.

*Medical Jurisprudence.*—Thomas Arnoldus du Toit, Andrew Gold, Douglas Chieuc Scotland, Thomas Dier, George Murray Shaw Lindsay, William Grant, Henry Godfrey Fitzmaurice, Jessie Melville Lyall Wright, Joseph Butler Dobson, James MacCoshan, James Sydney Alexander Rodgers, Robert Smith, and John Richard Larson.

**ROYAL COLLEGE OF SURGEONS OF EDINBURGH.**—At a meeting of the College held on July 11th the following candidates, having passed the requisite examinations between March 17th and 20th, were admitted Fellows:—

Joshua Isadore Baez, Robert Chalmers, James Erlank, Aubrey Scott Gillett, Eben Stuart Burt Hamilton, Maurice Bertram Lawrie, George Millar, Sengarapillai Ponniah, Alan Thomas Roberts, George John Chase Smyth, Harvey Henry Vincent Welch, and John Benson Young.

**UNIVERSITY OF ABERDEEN: GRADUATION CEREMONY.**—The summer graduation ceremony was held on July 11th, when Sir Douglas Haig and Sir Roger Keyes attended to receive the honorary degree of Doctor of Laws, which was also conferred upon Sir James Cantlie, Emeritus Professor John Theodore Cash, Sir David Hardie (in absentia), member of the Senate of the University of Queensland and late Lieutenant-Colonel, R.A.M.C., Sir James Porter, late Director-General, Naval Medical Department, and Dr. John Scott Riddell, Director of the North-Eastern District Red Cross Society. The following degrees were also conferred:—

### DOCTOR OF MEDICINE (M.D.).

Francis James Browne (highest honours for thesis), William Wilson Ingram (commendation), Alfred George Brown Duncan (honours), Archie Reith Fraser (honours), George A. Jam, Ratan Edulji Dastur, Andrew Smith Leslie, David Murdoch Marr, and Cameron Macdonald Nicol.

### BACHELOR OF MEDICINE (M.B.) AND BACHELOR OF SURGERY (CH.B.).

John Allan, Annie Anderson, William Anderson, Margaret Mitchell Chapman, James Sylvester Cook, James Clyne Trigue Crowden, Elizabeth May Dow, Dorothy Margaret Jane Emslie, William Alexander Falconer, John Fiddes, Alexander Coutts Fowler, Alexander E. I. Gammie (second-class honours), Coral Olive Gordon (second-class honours), James Innes Hutchison, Mary Victoria Littlejohn, Bethia Muir Newlan, Margaret Porteous, Lewis Stevens Robertson, Keith Sargent Roden, Irene Tomina Joan Ruxton, George Alexander Shepherd (second class honours), Henry Third, Atholl Thomas, and Louise Tomory.

\* Passed Final Professional Examination with distinction.

† Passed Final Professional Examination with much distinction.

The John Murray medal and scholarship were awarded to Dr. George Alexander Shepherd.

**UNIVERSITY OF DUBLIN, TRINITY COLLEGE, SCHOOL OF PHYSIC.**—At examinations held recently the following candidates were successful:—

### FINAL MEDICAL EXAMINATION.

*Part I, Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene, Pathology.*—Albert Victor John Russell (high marks), George Hall Davis (high marks), Theodore Kvitloff and Edmund Cyril Smith (equal) (high marks), Francis Victor Small, Joseph Hirschmann, Harold Osmond Holmeyer, John Frederick Wickham, Mervyn Edmund McBrien, Margaret Tate Stevenson, Cecil Emrys McQuide and Esie Stuart Smyth (equal), Emily Elapheth Grace Bailie, Barney Mosholowitz, Thomas Falkland Litton Cary and Nannette Norris (equal), William Richard Burns, John Henry B-nell Crosbie, and William Bruce Briggs.

*Pathology only (completing examination).*—James Alexander Acheson, *Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene.*—John Russell Craig, Francis Young Pratt, Robert Sturgeon Chapman, Thomas Gerald Warham, John Douglas Thompson, Albert Stanley Bradlaw, and William Harlan Smith. Richard Victor Dowse, John Carson Brennan, and Henry Allman Lavelle.

*Part II, Medicine.*—Cyril Daniel Brink, John Charles Joseph Callanan, William Frederick McConnell, and James Sinclair Quin (equal), Gerald Fitzmaurice Keatinge and Leslie James Nugent (equal), Jessie Gilbert, Mary Christina Sheppard, Thomas James Russell Warren, Eric Stuart Bwing Mack, Albert William Darnley Magee, and Samuel John Laverty, Henry Blundell Van der Merwe, and Victor George Walker (equal).

**Surgery.**—James Sinclair Quin, Albert Hugh Thompson, Richard Counihan, Cecil Joseph Quinlan, Thomas James Russell Warren, Gertrude Rice, Reoher FitzJames Haythornthwaite, Frederick William Godboy, Charles Goring Ambrose, William Joseph Hogan and Thomas Madill (equus), Patrick Casey, Frederick John Dymoke, and Albert William Darnley Magee.

**Midwifery.**—Leonard Abrahamson (high marks), Frederick William Robertson (high marks), John Gerard Holmes, John Henry Coolahan, Janie Millar Cummins, Harris Cohen, Cyril Daniel Brink, Hilken Hilda Dowse, Thomas Madill, Richard Edmonde Murphy, Thomas Donald Gordon, Francis John Gerard Battersby, Abgar Head Aldin, and Samuel Reginald Hill.

#### DIPLOMA IN PUBLIC HEALTH.

**Part II., Sanitary Engineering, Vital Statistics and Public Health Law, Hygiene and Epidemiology.**—Henry Cunningham Mulholland, Beattie Lyons, Robert Condy, Gilbert Marshall, Cecil William Clements Robinson, and Charles Ernest Moore.

**QUEEN'S UNIVERSITY OF BELFAST.**—At the graduation ceremony on July 9th a distinguished honorary graduate was Viscount Bryce, on whom was conferred the degree of LL.D. Sir David Semple, M.D., had the honorary degree of D.Sc. conferred upon him in recognition of his original researches in enteric fever, tetanus, and bacterial vaccine therapy. Lieutenant-Colonel Robert McCarrison received the honorary degree of LL.D. (in absentia) for his brilliant researches in goitre and the ductless glands, while Lieutenant-Colonel J. A. Sinton, V.C., received the honorary degree of M.D. in recognition of his early distinctions and of his valour in the field. The following degrees by examination in medicine were conferred:—

**M.D.**—Eileen M. Bell (with distinction and gold medal), Nathaniel Beattie, Joseph Corker, Caroline V. Lowe, James Lyons, and Peter P. Wright.

**M.B., B.Ch., B.A.O.**—William R. Abernethy, Samuel Ballantine, Hugh Carson, Thomas J. A. Connolly, Eric A. Davison, Samuel Hall, Benjamin Herbert, John M. Hovey, Daniel J. M'Gurk, William C. M'Kee, Thomas H. M'Kenna, Mary M. Merrick, Robert Nimmons, David G. Roulston, Alexander M'W. Segerdall, Ruth M. Slade, and Henry W. Wild.

**Diploma in Public Health.**—Ivlie Ald, John B. Alexander, Samuel T. Beggs, James Boyd, Llewellyn D. I. Graham, William M'Dermott, Edward B. C. Mayrs, Thomas Milling, Frederick A. E. Silcock, James Tate, Percival S. Walker, and George Wilson.

**THE SOUTH LONDON HOSPITAL FOR WOMEN.**—The third anniversary of the opening of the hospital was celebrated on July 9th, when purses representing a total collection of £700 were handed to Lady Carishrooke. Lady Londonderry, chairman of the board of management, drew attention to the fact that a sum of £7000 was required before the end of the year to meet anticipated ordinary expenditure.

**METROPOLITAN HOSPITAL SUNDAY FUND.**—The following are among the amounts received at the Mansion House up to July 11th, the total amount being then £56,000:

St. Columba's Church of Scotland, Pont street, £575; St. James's, Piccadilly, £380; Christ Church, Lancaster-gate, £236; Holy Trinity, Sloane-street, £278; St. Paul's, Knightsbridge, £227; St. Peter's, Eaton-square, £214; St. Simon's, Upper Chelsea, £173; St. Jude's, Kensington, £146; St. Stephen's, Avenue-road, £132; St. Stephen's, Gloucester-road, £130; Holy Trinity, Kensington Gore, £122; Greek Church, Bayswater, £121; Essex Church, Kensington, £119; St. Peter's, Cranley-gardens, £109; Christ Church, Mayfair, £103; Cannon Brewery Co., Ltd., £105; St. Mary in the Boltons, £103; Temple Church, £102.

**ROYAL MEDICAL BENEVOLENT FUND.**—At the last meeting of the committee, held on July 8th, 20 cases were considered and £200 voted to 15 of the applicants. The following is a summary of some of the cases relieved:—

Widow, aged 52, of L.S.A. Lond. who practised at Leyton and died in 1914. Receives £2 10s. per week from the sale of the practice, and £2 from children. Has five children, only the two eldest working, the third at home, and the two youngest at school. Requires help owing to the increased cost of living. Relieved four times, £35. Voted £10.—Daughter, aged 64, of M.R.C.S. Eng. who practised at Blackheath and died in 1881. Suffers from chronic ill-health and is entirely dependent on her sister, who applies for her. Her only income is £5 from investments. Relieved 14 times, £131. Voted £10 in two instalments.—Widow, aged 39, of M.D. Durh. who practised at Tamworth and died in 1917. Was left totally unprovided for with seven children, now aged 17-3 years. Only the eldest is working, and she helps all she can. Applicant receives £150 from dividends, and about £52 by letting rooms. Brother-in-law pays rent, and relations help a little with education. Relieved twice, £30. Voted £12.—Daughters, aged 43 and 47, of M.R.C.S. Eng. who practised at Poplar and died in 1892. They live on the West Coast and take in paying guests, and during the last 12 months have made £70. Rent and rates £79. They find it necessary to apply for help owing to the very short season in 1918, and the increased cost of living. Relieved six times, £60. Voted £10.—Widow, aged 53, of L.R.C.P. & S. Edin. who practised at New Quay and died in 1893. Applicant suffers from ill-health and is unable to work. Has two sons, who are both in the Navy, and help whenever possible. Pays £6 a year rent. Relieved 16 times, £161. Voted £18 in two instalments.—Daughter, aged 67, of M.R.C.S. Eng. who practised at Liverpool and died in 1885. Receives £30 from another charity and £7 from dividends. Lives with sister, and they share the rent, which is £17. Suffers from ill-health and deafness and is unable to work. Relieved five times, £58. Voted £18 in 12 instalments.—Widow, aged 65, of M.B. Dub. who practised at Acton and died in 1912. Applicant was left with four children, now all married and only able to help very slightly. She earns a little by needlework. Has let her flat for £2 2s. a

week until July 14th. Rent £50. Unable to manage owing to high cost of living. Relieved three times, £25. Voted £12 in 12 instalments.

—Widow, aged 70, of M.D. Glasg. who practised at Dennistoun and died in 1876. Applicant lives with married daughter and is too old to work. She receives £20 from another charity and £48 from children. Suffers from rheumatism and neuritis. Relieved five times, £60. Voted £18 in 12 instalments.—Daughter, aged 63, of L.R.C.P. Edin. who practised at Holloway and died in 1884. Only income £40 a year from another charity. Suffers from ill-health, which prevents her from working. Rent £41. Relieved 15 times, £139. Voted £18 in 12 instalments.

Subscriptions may be sent to the acting honorary treasurer, Dr. Samuel West, at 11, Chandos-street, Cavendish-square, London, W.1.

Sir Arbutnot Lane, on the invitation of the committee of the French Hospital, Shaftesbury-avenue, will act as senior surgeon to the institution.

Mr. G. G. Henderson, M.A., D.Sc., LL.D., F.I.C., has been appointed Regius professor of chemistry in the University of Glasgow in the room of the late Professor John Ferguson.

**THE LATE DR. ARTHUR FULLER.**—Dr. Arthur Fuller, who died at Kimberley on June 2nd, was a well-known citizen, having long been a member of the hospital board and school board. He was at the time of his death President of the South African Permanent Mutual Building and Investment Society.

**THE CHEMISTS' EXHIBITION.**—More than usual interest was taken in the Chemists' Exhibition opened at the Northampton Institute, Clerkenwell, on Monday, July 14th, inasmuch as the occasion marked the revival of a demonstration held annually previously to the war. A period had elapsed, therefore, in which pharmaceutical developments had taken place, and a stimulus had been given to the preparation of so many drugs not before made in this country. These facts made the exhibits peculiarly attractive and served to swell both the number of exhibitors and visitors. Pride was manifest in British manufactures, and the various products shown were a proof that foreign monopoly in this section of industry need no longer exist. Altogether the exhibition was a credit to the great British drug houses, and it is to be followed by a medical exhibition to be held in the Central Hall, Westminster, from Oct. 6th-10th next.

**A CREMATORIUM FOR THE CAPE.**—The Health Committee of the Capetown Town Council, having had remitted to it for consideration the subject of the establishment of a crematorium in the city, reports that the method of disposing of dead bodies by cremation is, there is no doubt, the most sanitary, but that if a crematorium is to be established it should be under the control of the Burial Board, and not of the municipality. The city council apparently not possessing powers to establish a crematorium, it would be necessary for special legislation to be enacted to enable one to be instituted. In submitting a report from the medical officer of health on English cremation procedure, the committee recommended that the matter be brought to the notice of the Minister of the Interior, Sir Thomas Watt, with a view to a Bill being submitted to the Union Parliament under which a crematorium could be established. The question will be considered by the Cape Municipal Association at the session to be held at Mossel Bay.

**MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.**—The annual meeting of the association will be held from Tuesday to Thursday, July 22nd to 24th, at York, under the presidency of Dr. Bedford Pierce. On Monday, July 21st, the council will meet at 5.30 P.M. at the Medical Society's Rooms, 17, Stonegate, York. On Tuesday the annual meeting will commence at 11 A.M. at "The Retreat," when the following officers will be proposed for the year 1919-20:—President: Dr. Bedford Pierce. President-elect: Dr. W. F. Menzies. Ex-President: Lieutenant-Colonel John Keay. Treasurer: Dr. James Chambers. Editors of Journal: Dr. J. R. Lord and Dr. Thomas Drapes. General Secretary: Major R. Worth. Registrar: Dr. A. A. Miller. A paper will then be read by Dr. G. R. Jeffrey entitled "Notes on a Case Treated by Hypnotic Suggestion." At 3 P.M. prizes and medals awarded during the year will be presented, and the presidential address will then be delivered by Dr. Pierce. Dr. G. L. Brunton will read a paper entitled "Notes on the Cytology of the Cerebro-spinal Fluid." The annual dinner will take place at 7.30 P.M. at the Station Hotel, York. On Wednesday, at the Bishop's Room in St. William's College at 10 A.M., papers will be read as follows: "The Value of Treatment by Psychological Analysis," by Dr. J. W. Astley Cooper; "An Analysis of 200 Cases of Mental Defect," by Dr. J. E. Middlemiss. Wednesday afternoon and Thursday are devoted to social entertainment of which a special programme has been issued.

## The Services.

### THE CASUALTY LIST.

THE names of the following medical officers appear among the casualties announced:—

*Accidentally killed.*—Capt. R. C. Dickson, R.A.M.C. (S.R.), qualified at Edinburgh in 1911, and joined the R.A.M.C. shortly afterwards.

*Died.*—Lieut. Col. J. Gould, C.B.E., I.M.S., was a student at University College, Liverpool, and qualified at Manchester in 1890, and joined the I.M.S. shortly afterwards.

#### Casualties among the Sons of Medical Men.

Lieut. G. Allison, Gurkha Rifles, killed in action on the Indian frontier on June 8th, 1919, elder son of Dr. T. M. Allison, of Newcastle-upon-Tyne. Second Lieut. G. M. Dickson, Black Watch, killed in action in France, October, 1918, and Capt. R. C. Dickson, R.A.M.C. (S.R.), accidentally killed on service in India, June, 1919, sons of the late Dr. G. C. Dickson, of Carnoustie, Scotland.

### THE HONOURS LIST.

The following awards to medical officers are announced:—

*C.M.G.*—Surg.-Cmdr. J. Chambers, R.N., for valuable services as operating surgeon at the Royal Naval Hospital, Chatham, since December, 1915.

*O.B.E.*—Surg.-Cmdr. R. H. J. Browne, R.N., for valuable services as principal medical officer on the staff of the Vice-Admiral Commanding the Battle Cruiser Force. Surg. Lt.-Cmdr. E. L. Markham, R.N., for valuable services in H.M.S. *Caradoc*, 6th Light Cruiser Squadron. Surg.-Cmdr. F. W. Parker, R.N., for valuable services as senior medical officer, R.N. Sick Quarters Invergordon.

*D.S.O.*—Surg. Lieut.-Cmdr. N. S. Meiklejohn, R.N., for distinguished services in H.M.S. *Caledon*, as Senior Medical Officer, 1st Light Cruiser Squadron.

*Military Cross.*—Temp. Capt. John Campbell, R.A.M.C., for conspicuous gallantry and devotion to duty north of Sherqat, on Oct. 27th/28th, 1918; he showed great skill and a total disregard of danger in tending the wounded under fire; on several occasions, owing to the intensity of the enemy's fire, he had to move his aid-post, but in spite of all difficulties he managed to evacuate all cases successfully.

The name of Surg.-Lieut. W. A. Mallam, R.N.V.R., has been brought to the notice of the Admiralty for valuable services in the prosecution of the war.

*Foreign Decorations.*—*French.*—*Croix de Guerre.*—Col. J. D. Alexander, D.S.O.; Bt. Lt.-Col. (temp. Lt.-Col.) E. B. Bird, D.S.O., R.A.M.C. (T.F.); Temp. Capt. (acting Maj.) A. J. Blake, M.C., R.A.M.C. (T.F.); Temp. Capt. (acting Maj.) A. W. S. Christie, R.A.M.C.; Bt. Col. (temp. Col.) H. E. M. Douglas, V.C., C.M.G., D.S.O., R.A.M.C.; Capt. (acting Lt.-Col.) W. R. Gardner, D.S.O., R.A.M.C. (S.R.); Capt. C. F. Hacker, M.C., R.A.M.C.; Capt. W. J. Knight, M.C., R.A.M.C.; Lt.-Col. (temp. Col.) L. N. Lloyd, C.M.G., D.S.O., R.A.M.C.; Capt. S. McCausland, M.C., R.A.M.C. (T.F.); Temp. Capt. J. C. Ogilvie, M.C., R.A.M.C.; Maj. (acting Lt.-Col.) D. de C. O'Grady, R.A.M.C.; Capt. (acting Lt.-Col.) E. Phillips, M.C., R.A.M.C.; Lt.-Col. (temp. Col.) H. S. Robb, C.M.G., D.S.O., R.A.M.C.; Temp. Capt. (acting Lt.-Col.) L. D. Shaw, D.S.O., R.A.M.C.; Capt. (acting Maj.) J. R. N. Warburton, M.C., R.A.M.C. (S.R.).

*Greek.*—*Medal of Military Merit, 2nd Class.*—Surg.-Cmdr. T. W. Myles, R.N.

*The Territorial Decoration.*—The Territorial Decoration has been conferred upon the undermentioned officers of the Territorial Force:—Army Medical Service: Col. G. H. Edington. Royal Army Medical Corps: Lts.-Col. J. S. Warack, J. Smart, E. J. Cross, John McKie, Maj. (temp. Lt.-Col.) M. G. Brenner, Maj. (acting Col.) D. Horie, Maj. (acting Lt.-Col.) W. F. Roe, Majs. F. W. Bailey, H. Stallard, A. F. Rutherford, V. Howard, N. MacLaren, F. B. Jefferies, H. W. Pritchard, W. Bryce, A. C. Farquharson, F. J. Oxley, W. W. Jones, E. G. Stocker, J. Evans, B. Edenbrooke (T.F.H.), J. N. Macmillan, E. M. Dyer, C. J. Martin, H. F. Horne, Capts. (acting Majs.) C. T. Holland, A. P. Watson, Capt. and Qr.-Mrs. J. Boxall, J. H. Maund.

### ROYAL NAVAL MEDICAL SERVICE.

Surg.-Comdr. E. G. E. O'Leary is placed on Retired List at own request.

W. J. Morris and J. F. Pace to be Surgeon-Lieutenants.

### ARMY MEDICAL SERVICE.

Col. T. Du B. White is placed on retired pay.

Temp. Col. A. H. Tubby (Lieutenant-Colonel, R.A.M.C., T.F.) relinquishes his temporary commission on re-posting.

Temp. Col. Sir H. M. Rigby (Brevet Lieutenant-Colonel, R.A.M.C., T.F.) relinquishes his commission on ceasing to be specially employed and on re-posting.

Temp. Col. H. McI. W. Gray (Major, R.A.M.C., T.F.) relinquishes his temporary commission on re-posting.

### ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonels relinquish the temporary rank of Colonel on ceasing to be specially employed: E. W. W. Cochrane, L. N. Lloyd.

Major and Brevet Lieut.-Col. M. G. Winder relinquishes the temporary rank of Lieutenant-Colonel on re-posting.

The undermentioned relinquish the acting rank of Lieutenant-Colonel on re-posting: Majors R. E. U. Newman, E. M. O'Neill, R. F. M. Fawcett, W. J. Waters, H. H. A. Emerson, L. V. Thurston (on ceasing to command a Medical Unit); Capts. H. A. Harbison, G. P. Taylor, C. Clarke, F. R. Laing, A. J. Hickey, T. A. Weston, J. R. Hill, H. H. Leeson (on ceasing to command a Field Ambulance); Temp. Capts. J. G. Johnston, K. G. Fraser.

Temp. Lieut.-Col. E. G. Gauntlett (Captain, R.A.M.C., T.F.), relinquishes his temporary commission on ceasing to be specially employed and on re-posting.

The undermentioned to be acting Lieutenant-Colonels whilst commanding Medical Units: Majors A. S. Williams, E. M. O'Neill, A. M. Rose, (Brevet Lieut.-Col.) C. W. Holden; Capts. (acting Major) T. A. Weston, E. A. Sutton; Temp. Capts. (acting Majors) H. S. Dewar, K. G. Fraser.

Major E. E. Parkes to be acting Lieutenant-Colonel whilst specially employed.

Temp. Capt. J. B. Butler to be acting Major whilst specially employed.

The undermentioned to be Captains: Capt. W. H. Cornelius, from Spec. Res.; Temp. Capts. R. H. Lucas, P. J. S. O'Grady.

Late temporary Captain to be Captain: J. E. English.

Temp. Capt. F. F. Middleweek relinquishes the temporary rank of Major on ceasing to command troops on a Hospital Ship.

Lamont resigns. Lieut.-Col. C. H. Bensley, Inspector-General of Prisons, Central Provinces, has been appointed Acting Inspector-General, Civil Hospitals pro tem. The services of Major J. M. Holmes, Deputy Sanitary Commissioner and Health Officer, Imperial City, Delhi, have been replaced at the disposal of Government of India Army Department. Mr. T. Harvey, Sanitary Engineer, will hold charge of the office of Health Officer, Imperial City, in addition to his own duties. Col. M. C. MacWatt, Inspector-General, Civil Hospitals, Punjab, has been appointed Acting Director General, Indian Medical Service, vice Major-General W. R. Edwards, C.B., C.M.G., on leave in Kashmir. Major R. M. Dalziel, Superintendent of Central Jail, Multan, has been appointed officiating Inspector-General of Prisons, Punjab, relieving Major W. T. Finlayson. Major W. G. Hamilton has been appointed to act as Superintendent, Presidency Jail, during the absence on deputation of Lieut.-Col. F. S. C. Thompson. Major J. P. Lynch, R.A.M.C., has been appointed to hold medical charge of the Civil Station of Barrackpore, vice Capt. D. J. McLaren, R.A.M.C. Major E. O. Thurston has been appointed Civil Surgeon of Hooghly. Bt. Lieut.-Col. C. A. Gill has been reappointed Chief Malaria Medical Officer, Punjab, on reversion from military duty, relieving Major C. E. Southen, Chief Plague Medical Officer, Punjab, of the additional charge. The services of Major J. E. Clement, Superintendent, Central Jail, Lucknow, and A. W. Overbeek-Wright, Superintendent, Lunatic Asylum, Agra, are placed at the disposal of the Government of India Army Department. Major C. L. Dunn, whose services have been placed at the disposal of the United Provinces Government by the Government of India, has been appointed a Deputy Sanitary Commissioner.

## AUXILIARY ROYAL ARMY MEDICAL CORPS FUNDS.

The usual quarterly committee meeting was held on Friday, July 4th, at 11, Chandos-street, Cavendish-square, W., when 12 grants were made to cases in the Benevolent Branch for Officers, amounting to £298. Requests for relief should be addressed to the Honorary Secretary, Sir William Hale White, at 11, Chandos-street, London, W.1.

## DEATHS IN THE SERVICES.

A telegram from Aden reports the death of Colonel Jay Gould, I.M.S., C.B.E., formerly Deputy Director-General, I.M.S., Simla. Colonel Jay Gould only recently took up the appointment of A.D.M.S., Aden Forces. He was one of the best-known officers in the I.M.S. Formerly medical officer of the 14th Lancers and Central India Horse, he has been employed as a medical staff officer at Naini Tal and Simla.

## URBAN VITAL STATISTICS.

(Week ended July 12th, 1919.)

*English and Welsh Towns.*—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had been 10.0, 9.6, and 10.0 in the three preceding weeks, further rose to 10.1 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the annual rate was 10.0 per 1000, and coincided with that recorded in the previous week, while among the remaining towns the rates ranged from 2.8 in Leyton, 4.2 in Edmonton, and 4.7 in Gillingham and in Eastbourne, to 16.3 in Great Yarmouth, 18.5 in Rochdale, and 18.8 in Brighton. The principal epidemic diseases caused 117 deaths, which corresponded to an annual rate of 0.4 per 1000, and included 36 from infantile diarrhoea, 28 from measles, 23 from diphtheria, 15 from scarlet fever, 9 from whooping-cough, 4 from enteric fever, and 2 from small-pox. Measles caused a death-rate of 1.8 in Newcastle-on-Tyne; the 2 fatal cases of small-pox belonged to the metropolitan borough of Woolwich. There were 6 cases of small-pox, 1348 of scarlet fever, and 1068 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 2, 1236, and 980 respectively at the end of the previous week. The causes of 31 deaths in the 96 towns were uncertified, of which 9 were registered in Birmingham, 4 in London, and 3 in Carlisle.

*Scotch Towns.*—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality, which had been 11.0, 11.5, and 9.9 in the three preceding weeks, rose to 11.0 per 1000. The 225 deaths in Glasgow corresponded to an annual rate of 10.5 per 1000, and included 6 from whooping-cough, 3 from measles, 2 from infantile diarrhoea, and 1 each from enteric fever and scarlet fever. The 72 deaths in Edinburgh were equal to a rate of 11.2 per 1000, and included 3 from whooping-cough and 1 each from measles and scarlet fever.

*Irish Towns.*—The 102 deaths in Dublin corresponded to an annual rate of 13.1, or 0.4 per 1000 above that recorded in the previous week, and included 3 fatal cases of infantile diarrhoea. The 90 deaths in Belfast were equal to a rate of 11.7 per 1000, and included 3 from scarlet fever and 1 each from enteric fever and whooping-cough.

## Parliamentary Intelligence.

## HOUSE OF COMMONS.

WEDNESDAY, JULY 9TH.

*Venerable Disease at Hull.*

Mr. ROBERT YOUNG asked the Minister of Health whether he had investigated the circumstances attending the deaths of three men within 10 days after treatment for venereal disease at the Royal Infirmary, Hull; what was the drug used; whether it had the approval of his Department; and whether he could supply any information on these cases.—Dr. ADDISON replied: Yes, sir; the three cases occurred in May, and my Department instituted inquiry forthwith. No drug was used, the deaths in each case following on examination only. Fuller investigation is proceeding, and a report will be received in due course.

*Finances of Irish Hospitals.*

Mr. EDWARD KELLY asked the Chief Secretary to the Lord Lieutenant of Ireland whether the Richmond, Hardwicke, and Whitworth Hospitals, and the Westmoreland Lock Hospital, had hitherto been wholly supported by moneys appropriated by Parliament; whether he was aware that no payment had been made towards the support of these hospitals since April, 1918; that it had been found impossible to finance these institutions on the old grant; that the governors recently resigned; that there was at present no means of paying current maintenance expenses; and if he could say what steps the Irish Government had taken to avoid the necessity of these hospitals having to close down for want of funds.—Mr. MACPHERSON replied: Reference to the Vote for Hospital and Charities (Ireland) shows the estimated income of these hospitals, exclusive of the Parliamentary Grant. In the case of the House of Industry Hospitals, the income, apart from the annual grant of £7600, is estimated at £9206 for the current year. A payment of £3000 on account of this grant was made in April last and a payment of like amount will be made this month. The annual grant of £2600 to the Westmoreland Lock Hospital was paid in April last. Application has been made by the Governors of the House of Industry Hospitals for increased financial assistance from public funds and the Treasury have not seen their way to consent to any increase in the grant of £7600 a year. A further application for assistance has been received from the Board of Superintendence on behalf of the hospitals mentioned in the question and certain other Dublin hospitals that are aided from the Parliamentary Vote. This application is at present before the Treasury. The resignations tendered by the Governors of the House of Industry Hospitals have not been accepted, and the Irish Government has been advised that the responsibility for the management of these hospitals still remains with them.

THURSDAY, JULY 10TH.

*Medical Treatment of Soldiers.*

Lieutenant-Colonel WALTER GUINNESS asked the Pensions Minister whether he was aware that under existing regulations no provision was made for admission to suitable institutions of men discharged from the Army on account of neurasthenia, melancholia, and epilepsy in Ireland; whether melancholia cases brought on by shell shock and amputation of limbs had in consequence been admitted to lunatic asylums in Ireland where they were treated as pauper lunatics; and whether he would take steps to provide maintenance and treatment for such cases in special institutions.—Sir J. CRAIG (Parliamentary Secretary to the Ministry of Pensions) replied: There are two institutions in Ireland available for neurasthenics. As far as I am aware there are no epileptic colonies in Ireland with which arrangements for the reception of discharged men can be made, and it is therefore necessary to bring the few cases of epilepsy to England. Men are only placed in asylums if they are certified under the lunacy laws, and I am now arranging that men so certified shall be treated as Service patients.

Lieutenant-Colonel GUINNESS: What in effect will be the difference between the treatment of Service patients and the ordinary pauper patient?—Sir J. CRAIG: Oh! very great. Special arrangements will be made by the medical officers. There is a distinct difference between the two classes.

*Tuberculous Ex-Soldiers.*

Lord HENRY CAVENDISH-BENTINCK asked the Minister of Health whether he was aware that the East Midlands Joint Disablement Committee had 1282 cases of demobilised soldiers suffering from tuberculosis in their area; and whether, in order to provide concurrent training and treatment on the colony system for these men, they applied in October, 1918, to the Pensions Ministry and later to the Local Government Board for financial assistance, but could get no more satisfactory reply than that both Departments were discussing with each other the question of the

treatment of tuberculous discharged men.—Dr. ADDISON replied: I have no recent information as to the total number of demobilised soldiers suffering from tuberculosis in the particular area referred to in the question, but I may say that the number of such cases in residential institutions on July 1st was 183, and the number on the waiting list was 24. The proposal to provide a colony for the concurrent training and treatment of tuberculous men in this area was first brought to the notice of my Department at the end of May when that particular subject of colony treatment had already been specially referred to the Departmental Committee set up by the Minister of Pensions and myself. Their report will, it is hoped, be issued very shortly, and I will then see that suitable steps are taken as soon as possible.

Lord H. CAVENDISH-BENTINCK: Will adequate and immediate steps be taken to carry out the recommendations of the Committee?—Dr. ADDISON: I must see what the recommendations are first.

FRIDAY, JULY 11TH.

#### *Income Limit under the National Insurance Acts.*

The report of the resolution declaring it expedient to raise the remuneration for exception from insurance under the National Insurance Acts from £160 to £250 a year was agreed to.

MONDAY, JULY 14TH.

#### *Scottish Board of Health.*

Mr. MACQUISTEN asked the Secretary for Scotland if he would state when the Scottish Board of Health was to be constituted in terms of the Act; whether, though unconstituted, it had been acting since July 1st; and whether he would give an assurance that nothing should be done by the Board as at present constituted except routine administration work, and delay all questions of appointments and arrangements for administrative duties until the Board was properly constituted.—Mr. MUNRO replied: I am advised that the Board was duly constituted under Section 1 of the statute, with powers duly exercisable as from July 1st. Its personnel is now complete. Meanwhile only duties of the routine kind referred to by my honourable and learned friend have been discharged.

#### *Tuberculosis Treatment.*

Mr. FOREMAN asked the Minister of Health if he could inform the House of the number of persons in the County of London suffering from tuberculosis known to the authorities to require sanatorium treatment and for whom no accommodation was available, and to see whether steps could be taken to utilise as sanatoriums auxiliary or other war hospitals no longer required for war casualties.—Major ASTOR (Parliamentary Secretary to the Ministry of Health) replied: The figures necessarily vary from week to week. There are approximately, as far as the County of London is concerned, some 1700 persons, including children, in residential sanatoriums 500, of whom more than half are children, awaiting entrance. All possible steps are being taken since the diminution of the difficulties occasioned by war conditions to increase the accommodation, including the adaptation of buildings that were provided for war purposes as far as these can be made suitable.

Dr. DELVIN asked the Pensions Minister whether his attention had been called to the treatment of discharged soldiers suffering from tuberculosis; whether he was aware that these men were unable to procure employment because of the disease they suffered from, as no employer wanted consumptive workmen; and whether he would arrange that these men were therefore allowed the full 100 per cent. disablement pension to help them to exist during the few years they might expect to live.—Sir J. CRAIG (Parliamentary Secretary to the Pensions Ministry) replied: The question of tuberculosis as affecting discharged soldiers has recently been considered in all its aspects by an inter-Departmental Committee. Their report is expected within the next fortnight and will be immediately taken into consideration.

#### *Artificial Limbs.*

Sir DONALD MACLEAN asked the Pensions Minister whether he would consider the advisability of publishing from time to time in the daily press photographs or sketches of the latest improvements in artificial limbs, so that men disabled in the war might have the latest information for the purpose of enabling them to minimise, as far as possible, the effects of their disability.—Sir J. CRAIG replied: My right honourable friend is obliged to the right honourable Member for his suggestion, and will consider how far it is practicable. Arrangements are being made to exhibit at repair depôts the various artificial limbs available, so as to give a choice of limbs within limits approved by the surgeons to the disabled men.

Sir D. MACLEAN: Will the honourable gentleman let me have a letter, or will he publish a list of these repair depôts, so that disabled men can have an opportunity of knowing

where they can go for their information?—Sir J. CRAIG: My right honourable friend is much obliged to the right honourable gentleman for his suggestion, which is quite valuable. In connexion with this and other schemes I am sure he will be only too glad to give the information.

#### *Ad hoc Dental Committee.*

Mr. SEDDON asked the Secretary of State for the Home Department whether the ad hoc Committee recommended by the Departmental Committee on Dentistry had been selected; and whether all existing societies of dental practitioners would be included in the selection.—Mr. SHORTT replied: No consideration has yet been given to the formation of the ad hoc Committee referred to in the honourable Member's question. This is a matter that must obviously be postponed until the legislation that will be necessary to give effect to the recommendations of the Dentists Act Committee is in a fair way of accomplishment.

## Appointments.

*Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BAXTER, C. B., F.R.C.S. Edin., has been appointed Honorary Assistant Surgeon to the Royal Berkshire Hospital.  
 FORSYTH, J. A. CAIRNS, M.Sc., M.B., F.R.C.S., Surgeon to the French Hospital, London.  
 LAKE, NORMAN C., M.D., M.S., D.Sc., F.R.C.S., Assistant Surgeon to Charing Cross Hospital.  
 LEWIS, THOMAS, M.D., F.R.C.P., D.Sc., F.R.S., Honorary Consulting Physician to the Ministry of Pensions.  
 LYONS, W. C., M.B. Edin., D.P.H., Assistant Medical Officer (Venereal Diseases, &c.), County Borough of South Shields.  
 MARTIN, DOUGLAS, M.B. Edin., D.T.M., D.P.H., Assistant Medical Officer (Tuberculosis), County Borough of South Shields.  
 MATHIESON, D. MORLEY, M.D. Edin., Ch.B., D.P.H., Medical Officer of Health, County Borough of Birkenhead.  
 OATES, G. E., M.D., B.S. Lond., D.P.H., Medical Officer of Health to the Metropolitan Borough of Bethnal Green.  
 STILES, Sir HAROLD J., to the Chair of Clinical Surgery in the University of Edinburgh.  
 WEAR, A. W., M.B. Durh., D.P.H., B.Hy., Assistant Medical Officer (Diseases of Children), County Borough of South Shields.  
 WHITE, H. V., M.D. Manch., Honorary Ophthalmic Surgeon to the Salford Royal Hospital.  
 French Hospital, Shaftesbury-avenue.—McCLURE, J. CAMPBELL, M.D., Physician to In-patients; FORSYTH, J. CAIRNS, F.R.C.S., Surgeon to In-patients; CROOKSHANK, F. G., M.D., Physician to Out-patients; BROSSY, JEAN, M.D., Physician to Out-patients; ROWE, ROBERT M., F.R.C.S., Surgeon to Out-patients; McHOL, JAMES, F.R.C.S., Ophthalmic Surgeon to Out-patients; BRAUN, JEAN, M.D., Physician to Out-patients (Genito-urinary Diseases); HERNIMAN-JOHNSON, F., M.D., Radiologist.  
 Certifying Surgeons under the Factory and Workshop Acts: KNOWLES, R. O., M.D. Liverp. (Birkenhead); ROBERTSON, A., L.R.C.P., L.R.C.S. Edin. (Dumbarton).

## Vacancies.

*For further information refer to the advertisement columns.*

Birmingham General Hospital.—Res. M.O. £155. Asst. P. £50. Surgical Registrar. £200.  
 Birmingham, Selly Oak Infirmary and House.—Asst. M.O. £275.  
 Bolingbroke Hospital, Wandsworth Common, S.W.—H.S. £150.  
 Bournemouth, Royal Victoria and West Hants Hospital, Boscombe Branch.—Res. M.O. £250. Also Second Res. M.O. £200.  
 Brighton, Hove, and Preston Dispensary.—Res. M.O. £200.  
 Brighton, Sussex Throat and Ear Hospital, Church-street.—Asst. Hon. S. Bury County Borough.—Asst. M.O.H., Asst. Sch. M.O., and Asst. Tuberc. O. £500.  
 Bury St. Edmund's, West Suffolk General Hospital.—Res. H.S. £175.  
 Cairo, Egyptian Government School of Medicine.—Professors and Lecturers, ££1000 and ££600. Also Radiologist and Lect. in Radiology, ££500. Anaesthetist and Lect. in Anaesthetics, ££500, and Registrar and Tutor, ££600.  
 Canterbury, Kent and Canterbury Hospital.—Jun. Res. M.O. £150.  
 Capetown Free Dispensary.—M.O. £50.  
 Coventry and Warwickshire Hospital.—Hon. Surg. Staff.  
 Devonport, Royal Albert Hospital.—Res. H.S. £200.  
 Dorchester, Dorset County Council.—Asst. M.O. £400.  
 Dundee Corporation.—Asst. Tuberc. O. and Asst. M.O. £300.  
 Eccleall Bierlow Union.—Res. M.O. £600.  
 Edinburgh City.—Clin. M.O. under Venereal Diseases Scheme. £750.  
 Elizabeth Garrett Anderson Hospital, Euston-road.—Female Senior Asst. £200.  
 Exeter, Royal Devon and Exeter Hospital.—Sen. H.S. £250.  
 Gravesend Hospital.—H.S. £200.  
 Great Northern Central Hospital, Holloway, London.—Oph. S.  
 Hospital for Consumption and Diseases of the Chest, Brompton.—H.P.  
 Isleworth Infirmary.—Sec. Asst. to Med. Supt. £300.  
 Khartoum, Wellcome Tropical Research Laboratories.—Assistant Bacteriologist. ££600.  
 Leeds University.—Lect. in Exptl. Phys. £500. Demonstr. in Phys. £250. Demonstr. in Hist. £250.  
 Leicester Royal Infirmary.—Two Hon. Asst. P. and one Hon. Asst. S.

Liverpool, Fazakerley Sanatorium for Tuberculosis.—Asst. Res. M.O. £250.  
 Liverpool School of Tropical Medicine.—Asst. Lect. in Parasitology. £250.  
 Liverpool, Stanley Hospital.—H.P. and H.S.  
 London Hospital, E.—Surgical Registrar. Also First Asst.  
 Manchester, Ancoats Hospital.—H.P. £150. Also Hon. P. and Radiologist.  
 Manchester Northern Hospital for Women and Children, Park-place, Cheetham Hill-road.—Hon. Asst. P.  
 Manchester Royal Eye Hospital.—Jun. H.S. £120.  
 Middlesex Hospital Medical School.—Demonstrator. £200.  
 National Hospital for Diseases of the Heart, Westmoreland-street, W.—R.S. M.O. £100. Also Non-Res. M.O. £50.  
 New Zealand.—Path. and Bact. for Pub. Health Dept., Auckland. £700.  
 Otago University, New Zealand.—Prof. of Syst. Med., Prof. of Clin. Med. and Therap., and Lect. on Clin. Med. £600, £500, and £400 respectively.  
 Plymouth, South Devon and East Cornwall Hospital.—H.P. £140.  
 Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Temp. M.O. 1 guinea per attendance.  
 Queen Mary's Hospital for the East End, Stratford, E.—Hon. Aural S. Two Asst. Hon. P.'s. Also H.S.  
 Rossall School, Fleetwood.—Res. M.O. £250.  
 St. George's Hospital, S.W.—Two Cas. Officers. £150.  
 St. Helens County Borough.—Asst. M.O.H. £500.  
 Sheffield Royal Infirmary.—Asst. H.P. £150.  
 Smyrna Mission and Beaconsfield Memorial Hospital.—Medical Missionary. £250.  
 South London Hospital for Women, South Side, Clapham Common, S.W. Female H.S. £100.  
 Surrey Education Committee.—Sch. Dentist. £400.  
 Taunton, Somerset and Bath Asylum, Gifford.—Asst. M.O. £300.  
 Tingwall, Whitcness, and Wexdale Parish.—M.O. and Pub. Vac. £45.  
 Tottenham Maternity and Child Welfare Committee, Antenatal Clinic.—Female M.O. £11s. 6d. per session.  
 University College Hospital, Gower-street, W.C.—Res. M.O. £150.  
 Victoria Hospital, Tile-street, Chelsea S.W.—H.P. and H.S. £100.  
 West Riding County Council, Treatment of Venereal Diseases.—Asst. £550. Also Sch. Oculist. £450.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Ascot (Berks), Dundee (Forfar), Falkland (Fife), Lavenham (Suffolk), Llantfair Caereinion (Montgomery), Newhaven (Sussex), Nottingham, North (Nottingham), Scarborough (Yorks, North Riding), Tynemouth (Northumberland), Walsend (Northumberland), and Yetholm (Roxburgh).

## Births, Marriages, and Deaths.

### DEATHS.

FINCH WHITE.—On July 8th, after a few days' illness, of pneumonia following influenza, Finch White, M.R.C.S., L.R.C.P., Vanbrugh Park, Blackheath, London, and Killaloe, co. Clare, aged 47 years.  
 HOLDING.—On July 6th, at Hazeldene, Denny-road, Paignton, S. Devon, Charles Holding, L.R.C.P. & S. Edin., aged 48 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

### Communications, Letters, &c., to the Editor have been received from—

A.—Dr. A. Ashkeny, Brockenhurst; Dr. R. W. Allen, Lond.  
 B.—Mrs. C. R. Buxton, Lond.; Dr. A. Balfour, Lond.; Rev. T. P. Brocklehurst, Giggleswick; Surg.-Comm. W. Bastian, R.N.; Bristol University, Registrar of; *British and Colonial Pharmacist*, Editor of; Mr. I. Back, Lond.  
 C.—Dr. H. G. P. Castellain, Lond.; Dr. N. H. Choksy, Bombay; Mr. H. G. Commings, Lond.; Prof. R. P. Cathcart, Lond.; Major T. Cherry, A.A.M.C.; Mr. G. D. H. Cole, Lond.; Dr. F. G. Crookshank, Lond.; Dr. J. Cates, St. Helens; Mr. K. Cumming, Lond.

## Notes, Short Comments, and Answers to Correspondents.

### THE BATHS OF OLD LONDON.

BY SEPTIMUS SUNDERLAND, M.D. BRUX.

#### PART II.

##### Floating Baths.

The Folly, a "castellated houseboat," was usually anchored opposite Somerset House Gardens soon after the Restoration, and was used as a musical summer-house in part of the seventeenth and eighteenth centuries. Pepys visited this in 1668. It was generally fixed on the south side of the river, near the foot of Cuper's stairs, which led to Cuper's Pleasure Gardens, on part of which the present Royal Waterloo Hospital for Children and Women now stands. During the time of William III. and Mary (1689 to 1702) it was frequented by the fashionable classes, and on one occasion by the Queen. Later it became the resort of a low class of society, was allowed to fall into decay, and was broken up about 1750. It is probable that at one time it was also used as a floating bath.

John Timbs, writing in 1863, mentions the fact that there were two floating baths upon the Thames "in our day," and says that in plan they were somewhat similar to *The Folly*. One of these was situated near Hungerford Bridge, for bathers of both sexes, and contained filtered water.

##### Sweating Baths.

In England in the thirteenth century the hot-air or vapour baths introduced by the Crusaders were given in establishments called "hot-houses" and were much in request, as were similar ones in the large cities of Europe. The hot vapour baths were tried for leprosy, which was prevalent in those days, as well as for syphilis, but with bad results. There were separate baths for lepers. Shakespeare and Ben Johnson mention sweating baths in their writings as "hot-houses." In the old play, "The Puritan," one of the characters, referring to an arduous undertaking, says, "Marry, it will take me much sweat; it were better to go to 16 hot-houses."

In the year 1517, when there was the second epidemic of the "sweating sickness" in England, the English were accused of gross feeding, of much intemperance, and of causing relaxation of their skins by spending so much time in hot-air baths. This shows that these baths remained popular in England at a time when they were beginning to be less used abroad. Later in England there were periods of comparative disuse until the end of the seventeenth century when they reappeared and became popular in London under the Italian name of "bagnios" (place for sweating) or the Arabic name of "humnum" (a warm bath); these were on the principle of the Roman hot-air or vapour baths. The various bagnios or humnums established in London appear to have become of doubtful repute, and frequented by evil characters; these circumstances led, after a time, to the suppression of the institutions. The practice of cupping was prevalent in those days and for a long time afterwards, associated with hot baths.

The Duke's Bath or Bagnio, minutely described in 1633 by Samuel Haworth, M.D., Physician to James II. when Duke of York, as "erected near the west end of Long Acre in that spot of ground called 'Salisbury Stables,'" was a stately oval edifice, paved with marble, and within the wall were ten seats, such as were formerly in the baths at Bath. When the Duke of York came to the throne in 1686 these baths were improved and reopened as the King's Bagnio, and an advertisement then stated "there is no other bagnio in or about London besides this and the Royal Bagnio in the City," the reference to the "Royal Bagnio" being in all probability intended for the bagnio in Bagnio Court, described below.

The Bagnio (the Royal Bagnio) in Bagnio Court (altered to Bath-street in 1843), Newgate-street, was built by Turkish merchants, and first opened in December, 1679, for sweating, hot bathing, and cupping; 4s. was the charge to each person, and certain days were reserved for ladies. Strype wrote: "This bagnio is much resorted unto for sweating, being found very good for aches, &c., and approved of by our physicians." The cupola roof, and walls set with Dutch tiles, were described by Hatton in 1708. It was subsequently used as a cold bath. Dr. Frederick Gervis, of Torquay, informed me that about 1860 he and other medical students of the old St. Thomas's Hospital, Borough, often bathed in this cold plunge bath, which was lined with white marble and was fed by very cold clear water always flowing out of a well-carved white lion's mouth. It was at that time spoken of as the "King's Bath" and was situated in a court on the north side of Newgate-street.

The various bagnios and hummums were again suppressed, but later—namely, in 1765—vapour baths in Cheyne Walk were established by Dominichetti, which were used for a time, medicated with herbs. The Somerset Street Baths, similar to those instituted at Brighton by Mahomed as medicated vapour baths, were in use near the close of the eighteenth century and became popular for years. In "Metropolitan Improvements, or London in the Nineteenth Century," is a print dated 1823, showing the building where the Royal York Baths, Regent's Park, can be seen to this day in York Terrace. They were used until three years ago. The building now contains a fair-sized Turkish bath, with three hot chambers and a shampooing room, which was formerly supplied from a spring, and a rest room. There are also about 12 small bathrooms, with old-fashioned ordinary baths to which pumps are attached. Medicated baths used to be given in these rooms. In 1860 a handsome Turkish bath was erected in Victoria-street, Westminster, but has since been demolished. The Hammam, opened in 1862 in Jermyn-street, St. James's, has been popular for many years and still exists.

*Baths and wash-houses.*—It is permissible to add that baths and wash-houses for the working classes originated in 1844 with "an association for promoting cleanliness among the poor." A bath-house and a laundry were fitted up in Glasshouse Yard, East Smithfield. The association also gave whitewash and lent pails and brushes to those willing to cleanse their own dwellings. This successful experiment led to the passing of an Act of Parliament "to encourage the establishment of baths and wash-houses," of which there are so many at the present day.

(To be concluded.)

#### THE WOMEN'S HOLIDAY FUND.

AN appeal emanating from this fund, issued by the Bishop of London and others, pleads for assistance on behalf of poor women and their babies in need of a holiday but unable to afford to go away from home without help. "Never before, perhaps, in the history of this society," says the appeal, "have holidays been so much needed and desired. The strain and anxieties of the long war and the epidemics of influenza, which have left their mark on hundreds of homes, have brought many a poor hardworking woman very near to breaking point. Already applications have been received from women who have not had a holiday for 20 or 30 years, in some cases from those who have never had one in their lives." In 1913 1240 women and 155 babies were sent away, but during the last five years, owing to the high prices and the heavy railway fares, the work of the society has been much limited. Donations will be acknowledged by Miss Cooper, Secretary, Women's Holiday Fund, 76, Denison House, Vauxhall Bridge-road, London, S.W.1.

#### A PROPHECY OF AVIATION.

To the Editor of THE LANCET.

SIR,—In Henry Maty's "New Review; with Literary Curiosities and Literary Intelligence for the Year 1785" is noticed at some length a book with the title, "Symposia, or Table Talk in the Month of September, 1784, being a Rhapsodical Hodge-podge, containing, among other Things, Balloon Intelligence for the Years 1785, 1786, and 1787." Its publication shows that "flying" had distinctly a vogue in this country nearly a century and a half ago; and Dr. F. J. Poynton's very interesting "details" in THE LANCET of July 5th supports the fact. The following extracts are culled from Maty's "New Review" and taken from the "Table Talk":—

"We are happy to assure our readers that the Air Carriages are found to be of such utility, that they are daily increasing in number throughout the Kingdom: no less than fifty Balloons were at their moorings in the various inns in Reading, in their way from Bath to London."

Then follows a computation that 100,000 horses which had been engaged in town-to-town traffic were displaced by balloons, and consequently the price of grain had fallen considerably. Again, the officers of the packets conveying the "foreign and Irish mails" were petitioning for pensions, their services no longer being necessary. A traveller from India asserts that he had not suffered from heat when over the "burning sands of Arabia," as he could always "chuse an atmosphere agreeable to the heat of the climate." "Till the wild Arabs have adopted Balloons," he says, "this mode of travelling renders people secure from the plunder of those lawless marauders." A "grand Balloon race over Salisbury Plain for 10,000 guineas" is mentioned, as well as a "grand sweep-stake" between certain ladies, the odds being "greatly in favour of Lady —, she having been accustomed to soar above the clouds long before the invention of Balloons." A "Man of Fashion" writes a book of 6 vols. 12mo, entitled "Balloon Tales: Being an Account of a Variety of Intrigues carried on in the Air." Leather goes down in price, saddles, bridles, &c., not being wanted. Ox-beef and mutton touch 2½d. per lb. at Smithfield "owing to the diminution of horses

in this country." In France desertions from the Army are ascribed to the facilities offered by balloons, as also the "easy concealment and escape of villains of all denominations from the hands of justice." The effect of the change upon the medical profession is shown in the following quip:—

"We hear there will be a great sale of carriages belonging to the Physicians, Apothecaries, Surgeons, Corn-Cutters, and Quack-Doctors in this Metropolis, for it seems the Synod in Warwick Lane have come to a resolution, and have given orders accordingly, that all the above denomination of people, shall either walk or visit their patients in Balloons in future, as the rumbling of ebarlots is very afflicting to people in fevers and other disorders which affect the spirits; and moreover, as they will be relieved from the expense of keeping carriages, they are to lower the fee in future to half the present sum. We think the resolution redounds greatly to the honour of the College. Indeed, the fees of the Faculty have, of late years, been so exceedingly high, that few people could afford to be ill, and at the same time to be properly attended."

In a synopsis of the other contents of the book this item is curious: "Meditations on a Balloon, by Cadwallader Crnden, son to the renowned Alexander the Corrector." Search for information respecting Jefferies would be facilitated if Dr. Poynton had given the name in full.

I am, Sir, yours faithfully,

Westgate-on-Sea, July 12th, 1919.

W. R.

#### PEACE CELEBRATIONS AND PRECAUTIONS AGAINST FIRE.

WE are glad to note that the British Fire Prevention Committee of 8, Waterloo-place, Pall Mall, London, S.W.1, have issued a timely warning, pointing out the dangers of inflammable materials such as flags and hunting, celluloid, paper lanterns, and other decorative articles commonly used at a time of rejoicing. The public are well advised to bear these precautions in mind. Copies of the warning are obtainable upon written application at the above address.

#### THE "ADELAIDE" PATENT GARTER.

WE have had submitted to us an ingenious form of garter-suspender, which on the score of economy in material has an advantage over the method of suspending stockings from the shoulder or from the waist. A ribbon of elastic is formed into a figure of 8, the ribbon being kept in place where it crosses by a slotted tab of leather. The two loops having been superimposed they are drawn over the foot and adjusted respectively above and below the knee, the part where the ribbon crosses being placed in the space behind the knee. Means are provided for altering the size of the loops so as to fit the leg. The invention is quite comfortable in use, there is no undue pressure, and the stockings do not wrinkle or get out of place.

#### MEAL SERVICE IN MILITARY HOSPITALS.

THE problem of serving meals in a military hospital is much the same in the United States as in our Army, but in 1918 special attention was given in the United States to the need for avoiding waste of food. It was necessary that every man should have enough, but that no food should be wasted, as every ounce of surplus food was required for the peoples of Europe, hence the remark of Major R. G. Hoskins, "Every garbage can full of wasted food costs at least one human life," which shows how seriously the United States threw itself into the war. The *Military Surgeon* for March, 1919, shows that there are two systems of serving food in U.S. military hospitals, one is similar to our own, the meals being issued to the patients on their tables; the other, called the "cafeteria" system, in which the patients come into the room, pick up their plates, &c., from a table, and pass a counter where they make a selection of the food they desire, in nature and quantity, from the serving dishes, and then pass to the tables where they eat it. This is a copy of the method in those American restaurants called "cafeterias," where there are no waiters, but each patron walks to the counter and selects his "order" for himself. Opinion seems to be divided as to the system which gives the better result. Patients are instructed to leave at the end a "clean plate," and therefore not to take too much on their plates at first, but, if necessary, to come back for a second helping, and thus it is found that rather more food is eaten than if large helpings are given at first, as the plates, less loaded, look more appetising and encouraging. It is noted by Major A. G. Wilde that constant supervision is required in hospitals to secure that food is well cooked and attractively presented, as well as being properly varied. He also notes what everyone in charge of a hospital not rigidly in routine must have observed, that cooks are always anxious to get away and scheme to have the meals issued earlier than they are ordered, and that consequently the meals are apt to be cold when served.

Captain W. C. Stevenson, R.A.M.C., and Colonel A. E. Webb Johnson, D.S.O., have been appointed Knights of Grace in the Order of the Hospital of St. John of Jerusalem in England.

# Ariss and Gale Lecture

ON

## THE INITIATION OF WOUND SHOCK AND ITS RELATION TO SURGICAL SHOCK.

*Delivered before the Royal College of Surgeons of England*

By E. M. COWELL, D.S.O., M.D. LOND., F.R.C.S. ENG.,  
ASSISTANT SURGEON, CROYDON GENERAL HOSPITAL.

### INTRODUCTION.

MR. PRESIDENT AND GENTLEMEN,—The problems of "shock" have occupied the minds of both clinical and laboratory workers for many years, providing always one of the greatest anxieties the operating surgeon has had to face. Much has already been said on this subject and an extensive literature has gradually accumulated. In the present lecture it is my purpose to describe in some detail several observations which I have been able to make on the "initiation," pathogenesis or onset of wound shock in the trenches of the Western front.

The adoption of the idea that no human suffering should, if possible, be allowed to occur in vain; and that every opportunity should be taken by the clinical observer not only to relieve the individual, but also to consider the community at large, has been peculiarly applicable to the particular aspect of war surgery at present under consideration. From the first, in the experience of surgeons on the Western front, the mortality of the wounded from shock has been distressing. The question that occurred to the inquiring medical officer was, first, "What can I do for this case?" and, secondly, "What lines of preventive treatment can I suggest?" Now, we ask ourselves, "How can we apply our knowledge of wound shock to the advantage of civilian surgery?"

*Terminology.*—In order to avoid confusion in speaking of the condition of "shock" in war surgery I have introduced the term "wound shock."<sup>1</sup> This suggestion has been adopted by Professor W. M. Bayliss<sup>1</sup> and other writers, and has so far not been replaced. Lieutenant-Colonel W. B. Cannon rediscovered the Hippocratic term "exæmia," and has used the word as describing the fundamental pathological principle at work in producing the condition—i.e., the body is "drained of blood."<sup>2</sup> From time to time cases of death from pure shock may possibly occur, but in war surgery I believe no case has yet been reported where it was possible to exclude either macroscopic or microscopic anatomical damage in one of the vital organs. In the cases of shock met with in civil surgery there are almost invariably factors of severe tissue trauma, toxæmia, hæmorrhage, or psychical disturbance present, which our study of wound shock has shown to play such an important part in the initiation of the condition. I have had no personal experience of death from pure "nervous shock." Such deaths, I imagine, do not occur unless there is some latent cardiac weakness.

### METHODS OF OBTAINING CLINICAL DATA.

During the past three years many clinical notes with blood-pressure observations have been collected from patients arriving in from 2–24 hours at the operating centre (C.C.S.) after being wounded. As a rule, if they were going to develop, the symptoms of wound shock were present on arrival at the hospital, and nothing was known as to the exact order in which they had supervened. It was decided, therefore, to establish the time relations of the onset of the condition.

A series of observation posts was organised, beginning at the various points in the firing line, where the man might be wounded, back through a series of relay stations, until finally he reached the hands of the surgeon. As he passed through each place notes were made on a card attached to the patient, together with details of the pulse-rate and blood-pressure readings, taken by means of a spring sphygmomanometer. I accompanied some of the most important cases through the whole journey, and made records at frequent intervals. At different points of the firing line studies of normal soldiers were made under varying conditions. Occasionally I was able to follow through a case whose blood pressure I had observed shortly before the wound was

No. 5004.

received. The main result of this work was the classification of the shock cases into primary and secondary, the details of which will be referred to later.

### PHYSIOLOGICAL STUDIES OF THE FIGHTING SOLDIER.

In order to investigate the factors which might be present before the man was wounded, and which might predispose to wound shock, I spent some time living in the trenches, watching the soldier under different circumstances, and taking blood-pressure observations as often as possible. The average maximum systolic pressure was found to be 110–125 mm. of mercury and the diastolic or minimum 75–80 mm. In the unwounded the variations were those of hypertension, and were generally found in men subjected to stress or excitement.

Perhaps one of the most fascinating subjects in physiology is the study of the reaction of the body to excitement. Of the psychical stimuli which result in extensive physiological processes, that of the excitement of battle probably comes first, converting the normal human machine into a fighting mechanism. Cannon,<sup>1</sup> and also Elliott,<sup>2</sup> found that, as the result of excitement in cats, sympathetic stimulation set free adrenalin, which could be detected in the circulation soon after the initial stimulus was applied. The main effects of this circulating adrenalin are to increase the heart-rate, raise the blood pressure, set free glucose from the liver in response to the demand of the muscles for more foodstuff, inhibit the movements of the alimentary canal, and diminish the coagulation time of the blood. The utility of these bodily changes is obvious, enabling the man to do more muscular work, withstand fatigue longer, and, in the event of his being wounded, hastening hæmostasis. As will be shown later, it is possible, however, that the secretion of adrenalin over a prolonged period may be harmful, and that prolonged excitement may prove to be one of the factors in the initiation of wound shock. The observations I have been able to make on the effects of excitement on soldiers show that a stimulus such as exposure to the danger of enemy fire, produces a reaction which, as might be expected, varies greatly according to the individual. Intellectual development, temperament, habitual exposure to danger in war or civilian occupation, and fatigue, all have a bearing on the physiological reaction as estimated by the sphygmomanometer. The effect of temperament is shown in the following cases.

At 2 A.M. on a dark night in the autumn I was able to collect records from sick men in a battle aid-post situated in a well-known sector of the line. (Fig. 1.) The men under observation were all slightly wounded and had just dropped back into the trench after having "gone over the top" on a raid. The artillery and machine-gun fire to which they had been exposed was severe. The men were, in civil life, farm labourers of particularly phlegmatic temperament.

No. 1.—A slight wound of the face. The man took everything as a matter of course, and sat quiet without speaking. Pulse 76. B.P. 115 mm.

No. 2.—Bullet wound of the hand; some pain. This man was talkative; later sang and showed signs of mild excitement. Pulse 126. B.P. 130.

The other four men had all come in at the double and were panting when first seen. Pulses and respirations slowed quickly on resting.

No. 3.—Slight wound of chin. R. 36. P. 144. B.P. 115.

No. 4.—Perforating bullet wound of arm. This man was rather pale, but was quite cheerful, and had not lost blood. Pulse 120. B.P. 120.

No. 5.—Slight bomb wound of the buttock. P. 124. B.P. 115.

No. 6.—Slight wound of the face. This man was of less robust physique than the others and looked in a bad way, with a pale face and weak voice. He wanted to lie down, having given in completely. There was no serious wound to account for this. P. 112. B.P. 120.

### *Observations on Garrison of a Detached Outpost.*

A few weeks later I was able to take advantage of the full moon to collect blood-pressure records of a garrison of a detached outpost situated in a new part of the line that was somewhat exposed. The men were organised into a series of posts, where they had been on duty for four nights and four days, with only brief snatches of sleep in the daytime. The nights were cold, and although the men were well fed, the water ration was only 10–15 oz. per man per diem. The following figures were written down in the order in which the readings were made. When the enemy fire came within a few yards a note was made as shown on the chart. (Fig. 2.)

Post.	B.P.	Remarks.	Post.	B.P.	Remarks.
1	118-80 126-90 116-80	Quiet.	6	136-85 120-80 120-80 140-80 120-75 130-80 110-60 120-65	Quiet. Several Very lights.
2	120-80 116-75 140-80	Fairly quiet.	7	110-80 (c) 120-60	(e) Two years in the line.
3	150-90 150-90 150-80 140-70 140-70 150-90 (a) 140-90 (a)	In sap leading to enemy's lines. (a) Two last men just knocked down.	8	138-80 130-75 120-85 130-90 130-80 124-70 (f) 136-70	Important M.G. position. (f) Very cold.
4	118-70 140-90 140-80 150-90 (b) 130-90 130-90 140-90 120-90 (c)	Quiet, but not very far away from 3. (b) N.O.O. in charge. (c) O.C. on his round.	9	140-90 130-80 110-60 120-90	Slightly active.
5	120-80 120-80 120-90 126-76 128-75 130-90 (d)	Quiet. (d) Sergeant.	10	160-90 150-90 120-70 104-70 (g)	Sentries at Coy. Hqrs. (g) Two years in the line.
			11	118-80 130-90 116-60	Stretcher-bearers and guide.
			12	130-90 140-90 118-80 140-90	Patrol party after 1½ hours march in the trenches.

The evidence provided by these readings seems to afford clinical support to the experimental observations of Cannon and Elliott, already referred to. It will be seen on examining the chart that at the posts where there was special danger there the men were found to show the greatest reaction. A large number of blood-pressure observations were taken of men of all ages and regiments in different parts of the forward areas in quiet times. The average was found to be 125-110, or even lower occasionally. For the sake of comparison I have picked out at random the blood pressures of 12 groups of men and plotted them. (Fig. 3.)

#### BLOOD PRESSURE IN THE WOUNDED.

At the present I am dealing only with observations made in the line, as soon as possible after the man was hit. For readings made on later cases I must refer to the paper written by Fraser and myself in 1917. In the trivial wounds, while transient psychical disturbances sometimes result and the man becomes momentarily faint, the hypotension does not exist long enough to be measured. On the other hand, in slight wounds the pressure is more often raised. For example, a strong healthy young gunner was slightly wounded with a few shell splinters. He walked to the dressing-station and was seen half an hour later. His face was flushed and his pressure was 180-100. Twenty minutes later it was 160-90, an hour later 126-80. His colour was now normal and he was sleepy. (Fig. 4.) Examination of large numbers of wounded make it possible to divide wound shock into primary and secondary varieties.

#### Primary Wound Shock.

Serious wounds do not always produce shock. Where, however, the damage sustained by the body is such that anatomical death must supervene unless surgical intervention is possible or available, the pressure falls with great rapidity and the symptoms of wound shock are found to have become established as soon as the patient is seen. In war surgery, at any rate, it is doubtful if such a state of affairs ever occurs apart from hemorrhage. To this class of case I have given the name "primary wound shock." It is an unavoidable condition, but one which in favourable cases may be kept from progressing and later terminate in recovery.

The following illustrative cases of primary wound shock may be quoted:—

(1) An ambulance driver, as he stepped off his car on arrival at the dressing-station one bright sunny morning, was hit in the abdomen by a shell fragment. He fell down, was carried in, and put on the dressing-table at once. As he was being attended to he drew the attention of the medical officer to his profuse sweating. I saw him 30 minutes later as he passed the next relay post on his way to the operating centre. He then complained of severe

pain, looked pale, and was still sweating profusely. His hands were cold and clammy, pulse 96, pressure 100-70. On arrival at the clearing station an hour later his pulse was only 100, but the pressure had further dropped to 82-70. Operation was immediately performed, hemorrhage stopped, and ten rents in the bowel repaired. The man's condition was serious for some hours, but he responded to treatment and eventually recovered. (Fig. 5.)

(2) On a cold, wet, muddy night a man was seriously wounded by a shell while digging a new trench. He was brought to the advanced dressing-station 50 minutes later and found to have sustained severe multiple wounds, including compound fractures of femur and humerus. The exposed lacerated muscle looked like dead tissue, there were no vessels of any size bleeding, and hardly any capillary oozing. The blood pressure was 40 mm. Mentally the patient was quite bright and responsive, so that the medical officer in charge of the case remarked how wonderfully fit he was. The man was dead, however, within the hour. (Fig. 6.)

#### Secondary Wound Shock.

In a large proportion of the serious wounds symptoms of shock supervene after the lapse of some hours. Early observations showed no alteration in pulse-rate or blood pressure level. During the next few hours, however, in the presence of certain factors, the pressure was found to fall, the pulse-rate to rise, and the state of shock to become established. To these cases I have given the name "secondary wound shock." I will first describe two cases where wound shock did not develop, although its onset might have been expected.

(1) One dark night the driver of a gun team was hit in the abdomen by a small shell fragment. He got off his horse to make inquiries for the dressing-station, and then rode nearly a mile before being seen by the medical officer. He was then quite fit, with a blood pressure of 120, which did not drop either before or after admission to hospital. At the operation two small rents in the small bowel were found and sewn up.

(2) One evening a man on a ration party was hit in the thigh by a shell fragment at the moment he was passing the entrance of the aid-post. He was carried down a few seconds later and found to have sustained a compound fracture of the femur. I found his pressure 120-80 and pulse-rate 72. He was immediately splinted and sent on to the dressing-station, where he remained under observation for six hours, and finally reached the casualty clearing station without at any time showing hypertension. (Fig. 7.)

In the next two cases the wounds were by no means serious in themselves, but secondary wound shock developed.

(3) A man belonging to the garrison, whose pressures are recorded in Fig. 2, was wounded by a bomb which partly shattered the forepart of his foot and sprinkled his neck and shoulder with tiny fragments. His chin, standing by his side, was killed. The blood pressure, which was 110-70 a short while previously, was still the same immediately after he was wounded. It was a cold night, with a chilly wind, and as the man was carried shoulder high along shallow trenches winding over a hill he became colder and colder. At this time, too, there was occasional enemy activity. By the time he reached the aid-post, an hour and a half later, he was pulseless. Two hours later, when examined at the next post, he was still pulseless and a serious view was taken of his condition. He was hurried on to the casualty clearing station, where he arrived with a pressure of 80-65 and no palpable pulse. After being warmed up in bed the pulse soon returned and the shock passed off in the absence of any heroic measures of treatment. (Fig. 8.)

(4) Early one night in October a young soldier on a wiring party sustained two simple perforating machine-gun bullet wounds through the fleshy part of the thigh. There was no extensive laceration of the muscles and no hemorrhage. After a two hours' carry in the cold I saw him at the aid-post. His condition appeared grave, his face was pale and cold, with blue lips and anxious expression. He complained greatly of thirst, presented a small, thready pulse and a blood pressure of 70-50. He was given a hot drink, well wrapped up, and sent on. In the next hour, while continuing his journey under these conditions, he recovered so well that the medical officer who made the next observations could not understand why I had been so anxious about the patient. By this time the pressure had risen to 120-80 and did not fall again. (Fig. 9.)

The following cases deal with amputation of limbs by gunshot wounds and the question of toxæmia playing a part in the onset of shock.

(5) When going down a communication trench about two o'clock one morning, I met a stretcher party carrying a man with his leg blown off. At the aid-post the patient was found to be a strong burly lance-corporal with some reputation as

a boxer in the battalion. He had been wounded about an hour before by a trench mortar, which had carried away his left leg a hand's-breadth below the knee, and at the same time severely injured the right tarsus. He lay quite calmly on his stretcher, and answered questions readily. The pulse was 96, and the systolic pressure 115. None of the symptoms or signs of shock were present; what little hæmorrhage there had been had stopped. The man was warmed, given as much cold water as he wanted, had his wounds dressed, was well wrapped up, and then sent on his journey. I followed him for the next three hours and took frequent pressure readings. When I left him his face had become flushed and the pulse-rate had crept up to 120, but the pressure remained level at 114-70. On arrival at the casualty clearing station an hour later his pressure had fallen to 88-62 and the pulse-rate risen to 144. The muscles of the stump were found to show signs of gas gangrene. After reamputation his condition improved, and he eventually recovered. (Fig. 10.)

This case I regarded at the time as an example of bacterial toxæmia. McNee<sup>9</sup> and others have drawn attention to the speed at which anaerobic infections may become established and produce their potent effects. Recent work by Bayliss and Cannon,<sup>1</sup> which will be discussed in detail later, introduces

the possibility of a new factor, that of absorption of the toxic products resulting from disintegration of muscle tissue apart from infection. In this, if immediate amputation had been performed, or at any rate a ligature tied round the stump to prevent absorption, the secondary wound shock would in all probability have been averted. In the next case this principle of treatment was adopted with success.

(6) A strong muscular soldier received a severe shell wound of the left arm, shattering the humerus. Within a

Chart of blood pressure of six phlegmatic soldiers after a trench raid.

Secondary wound shock, Case 3, bomb wound of neck and foot, not severe.

short time the medical officer in the trenches, who was familiar with the view expressed in the preceding paragraph, saw the man and performed immediate amputation under an anæsthetic, thereby removing all the traumatised tissue. Four hours later I saw the patient at the next relay post. He was pale but quite fit, with a maximum blood pressure of 140 and a pulse-rate of 90.

It has been frequently noted clinically that a patient under operation for removal of a shattered limb would show an increase in pulse-rate and respiration with lowering of

the blood pressure a few minutes after the tourniquet had been relaxed. Latterly we have taught that in cases where the application of a tourniquet was necessary the medical officer should apply it as near to the damaged tissue as possible, so as to allow of amputation with the original tourniquet in situ.

9

10

#### Relation of Primary to Secondary Shock.

Fig. 11<sup>a</sup> shows diagrammatically the possibilities in a case of primary wound shock. From a practical point of view the importance of closely watching the patient during the period immediately subsequent to the onset of shock cannot be too urgently insisted on. Otherwise the favourable moment, B, will be missed, and the primary merge into secondary shock without the patient being given the benefit or opportunity of surgical intervention. The behaviour of the blood pressure in secondary wound shock is charted diagrammatically. (Fig. 12.)

#### Aggravation of Wound Shock by Surgical Operation and Other Factors.

Marshall has published records of the blood pressure in the wounded during operation.<sup>10</sup> Here are a few illustrative charts from my own cases.

(a) This patient came into the hospital within 20 hours of receiving a gunshot wound with fracture of the right fibula. On admission the maximum pressure was 130, which fell to 120 at the end of the first operation. Next day gas gangrene developed, necessitating the amputation of the limb. After operation the pressure had fallen to 80. It was recognised that the cause of toxæmia was now removed, and that there was no hæmorrhage to treat. The patient was kept warm, given plenty of fluids, and in a few hours the blood pressure had completely regained its former level. (Fig. 13.)

(b) S. Major — was admitted 12 hours after sustaining a shell wound of the thigh. At the operation the fragment was found to have torn the femoral vein, and the patient lost a certain amount of blood before the vein could be sufficiently exposed to be sutured. The pressure fell from 118 to 90 mm., and in this case was immediately restored by an intravenous injection of gum saline. Fifteen hours later the shock-like condition, so often associated with the presence of gas gangrene infection, was observed. This necessitated excision of the affected muscle (sartorius) and a further intravenous injection of the gum saline. (Fig. 14.)

(c) During operation in gunshot wounds of the abdomen a fall of blood pressure may be produced by one of three conditions, as Marshall has pointed out.<sup>10</sup> 1. Manipulation of gut or omentum outside the abdominal cavity. 2. Occurrence of copious hæmorrhage. 3. Change of posture at the

end of operation from dorsal to lateral. Reference to Fig. 15 illustrates the last-named cause of sudden drop in pressure. This observation was made before I was aware of the possibility of such an occurrence.

#### SUMMARY OF RECENT INVESTIGATIONS.

##### Clinical Observations.

From the early clinical studies, which have already been described in detail, the factors which predominate in the pathogenesis of wound shock are:—

- (1) Pre-wound factors of fatigue, exposure, lack of fluids, and presence of excitement.
- (2) Post-wound factors of pain, hæmorrhage, cold, and absorption of bacterial or tissue toxins.

##### Pathological Studies.

The idea that the origin of shock was entirely due to the action of unknown psychical disturbances and vague nervous influences producing vaso-motor disturbances, which required to be controlled by such measures as the wearing of pneumatic suits, is now replaced by a more definite pathological picture. Recent investigation shows that in addition to arterial hypotension the following series of definite facts may be demonstrated in an established case of shock. 1. Capillary stasis and increased permeability of the vessel walls. 2. Reduction of the blood volume following hæmorrhage and factor (1). 3. Absorption of toxic products from infected or damaged tissues, or both combined. Possibly also toxæmia from hypersecretion of adrenalin. 4. Diminution of intracellular oxygenation, leading to irrecoverable damage of the finer nerve cells. 5. Presence of acidosis in the blood (reduction of the alkali reserve). 6. Profound lowering of body temperature. 7. Toxic action of certain anaesthetics. 8. Effects of hæmorrhage. The above factors form a symptom-complex of the nature of a vicious circle, rendering the condition once established extremely difficult to combat.

Examination of the body after death has revealed little of importance. The observations that are of value have been made by laboratory workers, who have been able to keep in close touch with the operating theatre, resuscitation, and post-operative wards.

(1) *Capillary stasis and permeability.*—Sherrington and Monkton, in 1893,<sup>11</sup> observed the concentration of the blood in shock by measuring the specific gravity and finding it increased. Marshall, in 1916, found that the hæmoglobin percentage was increased in the blood in cases of shock. Cannon and Fraser confirmed this in 1917, and found evidence of concentration of both systemic and capillary blood. The curve shown in Fig. 16 illustrates how quickly the pressure drops as fluid leaves the circulation in established shock.

(2) *Reduction of blood volume.*—N. M. Keith, and later O. H. Robertson, measured the blood volume directly by the vital red method, and have been able to construct curves of concentration and subsequent dilution of the blood during the period of recovery. This work has brought forward evidence as to the way in which fluid is best absorbed by a patient with a low pressure. "Forced fluids" given by mouth or rectum (O. H. Robertson) are often as efficacious as when administered intravenously. It is doubtful, in cases of shock with low pressure, whether subcutaneous saline is absorbed at all unless the condition is not severe or the patient is already recovering. This work solves the problem of the lost blood in shock. At any rate, in an established case the blood is not "pooled" in the splanchnic area, but is diminished in quantity because of its concentration.

(3) *Various toxic causes of shock.*—Clinical evidence for the support of the adrenalin theory has already been produced. (Fig. 2.) Experimentally Cannon and also Elliott<sup>4,5</sup> have demonstrated the presence of adrenalin in the circulating blood of animals under emotional stress. Bedford<sup>7</sup> has been able to show the presence of adrenalin in the blood of animals suffering from experimental shock. Bainbridge and Trevan<sup>6</sup> found that intravenous injection of small doses of adrenalin into an animal after 20 minutes induces the same concentration of the blood already described.

Dale's "histamine shock" opens up a large field of thought. Dale and his co-workers found that suitable doses of histamine (10 mgm. for a large cat) produce a profound drop in blood pressure, with capillary stasis and

11

Primary wound shock curves (diagrammatic). Following a severe anatomical injury, instant wound shock may develop, which may be fatal in a shorter or longer time, as shown at A or A'. Under favourable circumstances the pressure may rise to B, dropping later to C. At this point the primary has merged into secondary wound shock.

12

Secondary shock curves (diagrammatic). In many of the cases of moderately severe wounds the pressure will remain level at A. In others it falls with the establishment of secondary wound shock, B. At this point the patient may react quickly to treatment, C, or after more prolonged treatment at D, to E. In the absence of favourable circumstances, the pressure goes steadily down, and the case terminates fatally in from 12-24 hours, F.

13

subsequent concentration of the circulating blood. Smaller doses produce a vaso-dilation, for which evidence is produced to show that it is capillary in origin.<sup>15</sup> This work deserves consideration in conjunction with Bayliss's investigations on muscle trauma. Bayliss and Cannon<sup>1</sup> found that within an hour after producing a compound fracture of the femur in an anaesthetised cat signs appeared similar to those seen in secondary wound shock. The pressure gradually went down, pulse-rate and respiration increased, the blood became concentrated, and finally the animal died. This occurred just as rapidly when the limb was isolated from

14

the central nervous system, so that the possibility of its being due to the transmission of harmful afferent stimuli was negated. When, however, the returning blood stream was interrupted no lowering of the pressure resulted, and the animal remained in good condition until the clips on the vessels were removed.

As soon as the returning blood reached the body, down came the blood pressure. It is probable that some tissue poison is set free from the traumatic myolysis which has resulted, producing effects like histamine. This experimental work confirms the clinical observations made on the human subject. Two years ago I tried, unsuccessfully, to stop the onset of shock by inducing regional anaesthesia (nerve blocking).

#### (4) Intracellular suboxygenation.

—Mott<sup>17</sup> has examined the brains of cases of fatal wound shock, and found evidence of early cytolysis of certain of the cells of the cortex and basal nuclei. These, however, he considers secondary to the low blood pressure

16

Time A.M. 1.30 2.30 3.30 4.30

and not of primary origin. From clinical experience after the maximum pressure has remained at 60-70 mm. for from 4-6 hours, the patient cannot, as a rule, be resuscitated, even by blood transfusion. The damage to the finer cells from lack of tissue oxygen has been too great; in other words, the process of tissue death has advanced too far for recovery to take place. Haldane has suggested pushing the oxygen treatment. But even if pure oxygen were breathed the plasma will only carry 2 per cent. more oxygen than normally. Practically the treatment with oxygen has not been successful. Morphia, by depressing the respiration, increases cyanosis, especially in patients after hæmorrhage. Experience has shown that such cyanotic shock cases react extremely badly to ordinary methods of treatment, and the only possible way of increasing the oxygenation of the body is to give more oxygen-carrying material in the shape of hæmoglobin by blood transfusion.

(5) *Acidosis (acidemia Wright)*.—In 1917 a number of observations were made by Cannon,<sup>2</sup> using the v. Slyke apparatus, on the alkaline reserve of the blood in the wounded with low blood pressures. These findings were confirmed by others on cases of experimental shock. Since the alkali reserve was found reduced in direct relation to the drop in pressure, the question immediately arose as to whether this might not be one of the primary causal factors. While this was being decided experimentally, alkaline intravenous therapy was practised, undoubtedly with benefit in certain cases. This important question has now been settled and is fully discussed in Report No. 7 of the Shock Committee.<sup>13</sup> The results of the various sets of experiments may here be summarised.

(i) "Simple acidosis" in the sense of a reduction of the alkali reserve of the blood, even though it be severe and prolonged, does not cause shock, or indeed, any perceptible impairment of the circulation or other vital organs in the otherwise normal animal at rest.

(ii) In the case of animals subjected to hæmorrhage, histamine shock, injection of adrenalin or peptone, there was no evidence of the symptoms being modified by acidosis.

(iii) Experimentally in dogs it has been found (Cannon) that the pressure could be kept at 80 mm. for an hour without a reduction in the alkali reserve. Below 60, however, a reduction always occurred. After a 20 per cent. hæmorrhage a pressure of 80 mm. in an hour reduces the alkali reserve—i.e., produces acidosis. This evidence agrees with clinical observations already quoted.

(iv) Evidence is adduced by Wright and others<sup>13</sup> showing that the toxæmia of gas gangrene is accompanied by an acidosis.

Therefore, from a practical point of view, the acidosis is merely to be regarded as a symptom of the lowered blood pressure and defective circulation. If steps are taken to improve these the acidosis disappears. The benefits claimed clinically from hypertonic alkaline treatment would probably have been more striking if gum-saline had been used instead.

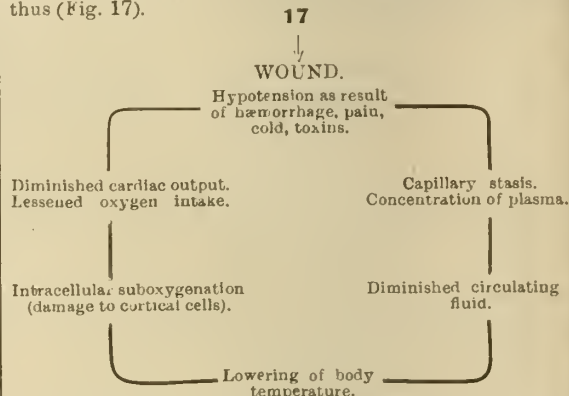

(6) *The body temperature in shock*.—Sufficient emphasis has been laid on the ill effects of cold. During a surgical operation, not only is the quantity of heat lost by the surface of the body increased, but the heat production itself is diminished. In a series of wounded presenting low blood pressures, the temperature taken of the interior of the thigh muscles was found to be as far below the normal as 94° F. and even occasionally lower. In this connexion it is interesting to note that Peter Lowe, writing on shock early in the seventeenth century, describes the condition as being due to loss of "vital heat."<sup>20</sup>

(7) *The toxic action of certain anæsthetics in shock*.—In the light of what has already been said on the lack of sufficient circulating fluid and deficient oxygenation of the tissues, it is obvious that the greatest care must be taken to avoid further depression of external or internal respiration. Buckmaster<sup>21</sup> concludes that chloroform combines with the corpuscles and directly interferes with their function of transporting oxygen from the lungs. One would expect a similar action with ether, but I believe this has not yet been worked out. Gas and oxygen anæsthesia, as advocated by Crile, Boyle, Lockhart-Mummery, Marshall, and others, does not possess this disadvantage, and either by itself or combined with some form of nerve blocking, is the only anæsthetic justifiable in all cases where hypotension exists.

(3) *Effects of hæmorrhage*.—Enough has already been said to show how serious is this factor. The circulating fluid in

shock is becoming diminished all the time and any further loss is not only felt directly, but speeds up the concentration process. O. H. Robertson considers that with a total hæmoglobin reduced to 25 per cent., transfusion (of blood) is indicated.

Any one of the above-mentioned factors may become the starting point of a vicious circle—expressed diagrammatically thus (Fig. 17).

*Gas*.—There is a condition which clinically and pathologically closely resembles that seen in shock—i.e., that found in men suffering from the effects of poisoning by a gas such as phosgene. Here the man is prostrated, blue and cold, with a weak pulse and low pressure. The same phenomena of blood concentration and increased viscosity are also present. A few of the cases of wound shock are undoubtedly complicated by gas poisoning; but for the most part gas does not play a practical part in the causation of shock.

#### COMPARISON OF WOUND SHOCK AND SURGICAL SHOCK.

Just as wound shock may be produced in a few minutes (primary wound shock), so in certain rare instances surgical shock may develop as the result of a sudden nerve stimulus, with or without hæmorrhage, or in an operation probably in association with an unsatisfactory state of anæsthesia. These instances are uncommon, and show themselves as cases of cardiac weakness or inhibition, demanding special treatment, such as cardiac massage.

The bulk of the cases of surgical shock, however, correspond to the common variety of wound shock—i.e., the secondary shock—the pressure falling towards the end of operation or even after the patient has been returned to bed. Undue anxiety, chilling, pre-existing bacterial toxæmia, or hæmorrhage are all pre-operative factors to be taken into consideration. During the operation further loss of heat, the amount and nature of the anæsthetic employed, the question of hæmorrhage, and, most important, the amount of trauma to which muscle tissue is subjected, all play a part in the production of secondary surgical shock.

With regard to tissue trauma, as Major-General Wallace has pointed out, the amount of shock resulting from a fore-quarter amputation, where the limb is removed along tissue planes, and where only a small muscular mass is divided, is, as a rule, small compared with the amputation through the hip-joint, where large muscular masses are traumatised. The beneficial effect of regional or spinal anæsthesia may, perhaps, be explained on these lines. There is complete relaxation, permitting of the handling and retraction of the muscle substance with the least amount of bruising and damage. The handling of the more important organs does not in itself necessarily produce shock. I have taken continuous pressure readings while the lung was being "externalised" and the hilum dragged on, without being able to detect any tendency to hypotension.

*Asphyxia pallida neonatorum*.—Buried under the obscurity of this ancient term is a variety of surgical or traumatic shock, to which very little attention has been paid. Here, for example, after being half-crushed and severely bruised in a case of difficult labour, the little patient is pale and flabby, with weak heart-beats and a failing circulation. In fatal cases hæmorrhages may be demonstrated in the muscles as well as in the viscera, all pointing to tissue trauma (Spencer). It would be interesting to know what changes are present in the circulating blood. Clinically such case

react well to warmth, the application of which in the form of a hot bath has been customary for many generations. In addition, in severe cases I found in 1910 that even normal saline injected intravenously often produced a rapid improvement. It is possible that Bayliss's gum saline, cautiously given in small doses, may prove of even greater value. The technique of intravenous medication in the new-born is simplified by the fact that the umbilical vein is patent and available, at any rate for the first half-hour of life. This method of treatment is probably widely practised, but I have been unable to find it referred to in the literature.

#### PRESENT CONCEPTION OF SHOCK.

J. P. Lockhart-Mummery, in his Hunterian lectures, 1905,<sup>20</sup> defined shock as a condition "resulting from a fall in general blood pressure due to exhaustion of the vaso-motor centre," and distinguished shock from collapse, where the "fall in general blood pressure is due to inhibition of the vaso-motor centre or loss of circulating fluid." In addition to the confusion arising from such a distinction there is no physiological evidence upon which such theories can even be based. If any difference in meaning is made use of between shock and collapse it should be one of time relationship rather than anything else. At the present time the term "collapse" is used to describe the symptom-complex resulting from the effects of more or less prolonged

rectum. If the pressure does not quickly rise gum saline is given intravenously. When it is thought that actual loss of blood is the chief factor, then transfusion of whole blood should be carried out with as little delay as possible. By these means the patient's condition can be sufficiently improved to allow of the surgeon performing anatomical repair and getting rid of toxic material.

3. During operation in such cases, or where the anatomical interference contemplated is at all extensive, the surgeon should insist on gas and oxygen either alone or combined with regional anaesthesia. During the operation a falling pressure may be counteracted by giving 500-1000 c.cm. 6 per cent. gum solution in normal saline. There is no evidence of any permanent benefit following the injection of pituitrin, adrenalin, ergot preparations, atropine, caffeine, camphor, strychnine, or any of the numerous drugs recommended from time to time.

[Drawings and diagrams were here shown illustrating some of the methods of treating the early stages of wound shock, as interesting some who have not had the privilege of treating the soldier in the trenches or on the battlefield.] (Fig. 18.) The greatest interest has been displayed by officers and other ranks of the R.A.M.C. since the commencement of the antishock campaign. In the latter days of trench warfare it was not possible to go into any well-established dressing-station, whether it was a converted

low blood pressure (Bayliss). Any vaso-motor disturbances that may be detected are transitory and of infinitely less value than the loss and concentration of circulating fluid. I would suggest from the practical standpoint the view that, with given causal factors, while primary shock is generally inevitable, secondary shock is mainly preventable. Reference to Fig. 18 will explain diagrammatically the present conception of shock and explain the symptom-complex.

#### General Management of the Case.

It was said in criticism of the papers by Cannon, Fraser, and myself<sup>3</sup> that the discussion of treatment was meagre when compared with the chapters devoted to clinical and pathological study. But once our knowledge of a morbid process is brought on to a sound clinical and pathological basis the application of therapeutic principles follows as a matter of course.

From what has been previously said, the surgeon in treating shock should bear in mind the following points.

1. The psychological aspect of the case. Any undue apprehension or excitement should be allayed by quiet persuasion, suggestion, or by the use of small doses of morphia if necessary.

2. The loss of circulating fluid and body heat. In preparing a case of shock for operation what has come to be known in war surgery as "resuscitation" is carried out. Warmth is applied by the most suitable means at hand, while the patient is made as comfortable as possible and allowed to rest. Fluids are freely supplied by mouth or

"pill-box," brewery cellar, or deep dug-out, without finding a well-organised method of combating wound shock.

In conclusion, I have to thank the authorities of the Royal Army Medical Corps for their ready assistance in making it possible for me to carry out these observations. Major-General Sir Cuthbert Wallace, K.C.M.G., C.B., Professor Bayliss, Dr. Dale, and the members of the Shock Committee, I wish to thank for their helpful advice. To Major-General Sir H. N. Thompson, K.C.M.G., C.B., D.S.O., I wish to express my gratitude for his sympathy and courtesy in giving the greatest possible help. Finally, I wish to thank the President and Council of the College for the honour of allowing me to have brought before you a subject so largely of interest to the military surgeon.

JAUNDICE AMONG THE BRITISH TROOPS  
IN NORTHERN ITALY.

BY H. H. TOOTH, M.D. CAMB., C.B., C.M.G.,

LATE CONSULTING PHYSICIAN IN ITALY;

AND

E. G. PRINGLE, M.D. LOND., M.R.C.S., L.R.C.P. LOND.,  
LATE CAPTAIN, R.A.M.C.*Note by H. H. T.*

In August, 1918, I saw with Captain H. G. Broadbridge, R.A.M.C., who was in charge of the "Signal Schools" Hospital at Valsanzibio, about 25 km. south of Vicenza, a group of ten cases from the signal schools camp in the mountains close by. They presented many features in common, as follows:—

Onset sudden without rigor, so sudden that the exact hour of the first symptom could be given in most cases. The first symptoms were "dizziness," a general feeling of illness, and headache, at first slight but growing in severity during the succeeding two or three days; this symptom was common to all. These men were admitted on the day of onset with temperatures of between 101° and 105°, and this fever was maintained with irregular fluctuations, but rarely falling to 100°, for 6-8 days, except in one fatal case in which it fell during the fourth day to 97.6°, and on the sixth and seventh, the day of death, to 96.6°. The pulse as a rule was not commensurate with the temperature; for instance, in one case the readings are T. 103.6°, P. 100, R. 30, and similar readings might be multiplied. The rapid respiration rate is suggestive of pulmonary complication, but I found no signs in those I examined. Pains general, or in the legs or back, occurred in eight. In nearly all suffusion of the conjunctivæ was noted as an early symptom, and in half of them soreness or redness of the fauces, and three showed herpes labialis. Of this group only one developed moderate catarrhal lung symptoms. In no case was the spleen or liver enlarged.

In addition to these cases Captain Broadbridge writes that shortly after this 18 more were admitted from the same source, and these he considered to be cases of so-called "epidemic pyrexia."

Taken as a whole, these two groups, totalling 28 cases, from one camp presented a general symptomatic similarity to the type of influenza which had been rife among the troops and civil population for some months previously. But among them, and in their onset and symptoms indistinguishable from the rest, were six cases (21.4 per cent.) which developed jaundice, and as jaundice was very common at that time they seem worthy of special notice. This jaundice appeared on about the sixth or seventh day of the illness, except in the fatal case in which it occurred on the fourth. Two of these I saw on my visit, and the others developed after it, but unfortunately I was prevented by illness from following them further.

Sapper G. H. D., aged 26, suddenly became "dizzy" and chilly at 6 P.M. on July 24th. He was admitted the same evening, with T. 101°, P. 102, and R. 22, headache and pains in the calves, and suffusion of the conjunctivæ appeared the next day. The fever was maintained at between 101° and 102.6° for four days, fell to 100° on the sixth, on which day he was jaundiced without any additional symptoms except for a crop of slightly raised purpuric blotches about the left loin and abdomen. With the fall of temperature the pulse-rate became abnormally slow, 46-66. He was transferred to No. 9 C.C.S. and from there evacuated to the base. No further notes are forthcoming, but from our experience we should suspect a continuance of low-grade fever.

Driver J. H., aged 20. Sudden onset with "giddiness" at 9 A.M. on July 26th, slight sore-throat and general pains. Admitted same day with a temperature of 102.4°, rising to 103.6°, falling suddenly to 97.8° on the morning of the third day, but rising again the same day to 101.6°. On the fourth day jaundice appeared and the temperature fell from 102° to 97.6°, and finally to 96.6°. The pulse-rate was 100 when the fever was at its highest, and respirations 30 without pulmonary signs. The jaundice became very intense, the tongue thickly coated white, and he suffered from repeated vomiting, intermittent headache, and severe general illness. No physical signs referable to heart, lungs, liver, or spleen were found at any time. He died in No. 9 C.C.S. on the seventh day of his illness. The post-mortem report is as follows:—"Acute pancreatitis. All tissues and organs deeply stained. The pancreas was swollen and hæmorrhagic. Inflammatory swelling around the orifice of the bile-duct, and also adhesion at the foramen of Winslow. No free fluid in the lesser sac. Liver, spleen, kidneys, and other organs apparently healthy except for bile-staining."

Most unfortunately no microscopical or bacteriological report on these organs has come from the laboratory owing to a change of pathologists at that time, and an important link which might have thrown light on this and the other milder cases is thus lost.

We have here, then, a group of 28 cases having common characters in the early stages, as to onset and symptoms and from the same place. Some of them develop jaundice, and, judged by the course of other cases to be detailed later by E. G. P., probably ran a long course of low fever. Others, the majority, are non-icteric. The icteric forms resemble clinically the spirochætal type. Have the non-icteric cases the same infective origin? Or are all influenzal, as one at first thought, with catarrhal jaundice as a complication. If so, why should such a simple complication so materially change and lengthen the further course of the disease? Or, lastly, have we two epidemic diseases occurring coincidentally?

I have but little information as to the later stages of this group, except inferential. One icteric case returned to duty in 18 days, an unusually short course. One died as reported above. Four were evacuated to the base or to France, and of these 1 only came under our observation subsequently. Of the non-icteric cases, 3 were evacuated to the base; of 12 there is no information. The remaining 7 were returned to duty from the local schools hospital or the C.C.S. after varying periods of stay in hospital—namely, 2 for three days only, 2 for 17 days, 3 for 18, 21, and 42 days respectively—an average stay of 17 days. Most of these periods are long for the type of uncomplicating influenza then prevalent.

The special interest to us in this group lies in the first-hand information at the earliest of a type of jaundice of which we saw a considerable number of instances in the later stages at the base, cases in which this information was very meagrely recorded on the field medical card.

In order to obtain some collective information on points such as are discussed in the following analysis, Colonel Howell, A.D.M.S., L. of C., caused reports on all cases of jaundice to be returned by medical officers of all units on L. of C. and base area during the months of September, October, and November, which also include a few in July, August, and December. As might be expected, these returns are very variable in value, but an analysis of them brings out some information after all reservation has been made. 128 returns of cases of jaundice came to hand, of these 17 were rejected, leaving 111 for consideration.

*Analysis of Returns.*

*Seasonal incidence.*—The greater number of cases occurred in the months of September and October, 58 and 38, respectively, 96 in all. In August 16, in July 3, in November 5, and in December 3, totalling 123 returns in which a date was given.

*Regional incidence.*—The greater number of returns are of cases occurring in the forward area—i.e., in the front line 12, or just behind it 16, the remainder being between this and Vicenza 21, and south of Vicenza 23, 2 from Padua. Thirteen came from places which cannot be identified on the map but were certainly in one of these regions, so that 92 came from the forward area (90 per cent.). Ten only came as isolated cases from places on the L. of C.

"Catarrhal" cases, 84 returns.—These are cases which are stated to have had no fever at any time, but included among them are three which had a very slight short rise above normal. The symptoms at onset in 41 are abdominal pain in the epigastrium and indisposition, nausea 7, general malaise 5, diarrhœa 2 only, headache and vomiting 13, vomiting 4, 72 in all.

Onset of jaundice from the first day of illness. Fifty-eight returns are available for this point. Fifty cases developed jaundice on various days from the first to the eighth, and of these 37 up to the fourth day, in 16 jaundice was practically the first symptom. Of these 58 cases the average day of onset was the fourth.

Where a record of the first appearance of bile in the urine is made this symptom, as might be expected, precedes the disappearance of the skin colouration by two or three days.

Date of reappearance of bile in the stools. This was noted in only 29 cases, and it is a very variable one, from the third to the twenty-first day. The average day is the twelfth, and that is probably an outside time.

Date of disappearance of icteric tinge from skin and conjunctivæ. This is a small point, but as a return was made

in 31 the figures may be mentioned. The largest number, 20, fell between the eighteenth and twenty-seventh days. The shortest period was 8 days from the onset of jaundice, the longest 31 days, the average being 21.

*Albuminuria* was recorded in 25 cases and absent in 42 in the 67 cases in which an examination was made. 44 returns are silent on this point. *Spirochaetes* negative, microscopically by inoculation in 2.

These returns of catarrhal jaundice are given for what they are worth. They came from all parts of the war area, but mainly from the more active forward area. They present elusive clinical features contrasting in this respect with the pyrexial group now to be analysed.

#### *Analysis of Pyrexial Group.*

*Jaundice with a definite pyrexial onset.*—A comparatively small but important group of 27 cases (24 per cent. of the whole number), it includes the cases referred to in E. G. P.'s note (*infra*), but not those of H. H. T.'s group in the first part of this article. The onset is noted as sudden in at least 14 of them, probably in all. In 17 the temperature is recorded as from 99° to 104°, and in those in which it was not recorded on the field medical card the symptoms were such that a high temperature was practically certain. Among the symptoms at onset were returned: abdominal pain, mostly epigastric, general pains, headache, epistaxis, sore-throat, vomiting, diarrhoea only in two.

Initial fall in temperature. This was noted in 17 cases, in 11 of which the fall took place on the fourth to the ninth day, the shortest period being the fourth, the longest the fourteenth day from the onset of the illness, giving as an average day the eighth. The fall of temperature, which generally marks the onset of the jaundice is followed by a short apyrexial period. This is returned in 14 cases, in 9 of which it lasted for from 2 to 6 days, the average period from these figures is 5·7 days, which is probably an outside estimation. The apyrexial interval is followed by a variable, but generally prolonged, period of irregular low grade fever, as described below by E. G. P., 19 returns give information on this point, but in some the temperature had not become normal at the time of the return, so that the average made is probably somewhat within the truth. The shortest period of secondary fever is given as 8 days and the longest is 57, the average being 33 days.

*Onset of jaundice.*—This was noted in all the 27 returns. In 20 of them the day of onset was from the third to the eighth, 10 being the third or fourth. The appearance of jaundice tends to precede that of the initial fall in the temperature, but that particular point is made in fewer cases. The average day of onset is the sixth (strictly 5·9). In the catarrhal group this day would appear to be earlier—i.e., fourth, average.

Reappearance of bile in the faeces dated from the onset of jaundice. As this is an indication of the duration of obstruction it is a fact of some importance, and a return was made in 19 cases, but unfortunately in about half of these the early note is defective, and it is only stated that at the time of admission to the unit in the base area the stools contained bile. The obstruction period is therefore certainly less than the figures at our command would warrant. It is disappointing that an observation so simple, and yet so interesting, should have been made in so few cases. With this reservation, in 15 the faeces were said to be bile-coloured in from 6 to 12 days after the appearance of the jaundice. An average of 8 days of obstruction for the 19 cases is probably too long, and 6 days is likely to be nearer the truth.

Disappearance of bile from the urine, noted in 16 returns to occur at all periods from the eighth to the forty-sixth day, gives an average day as the twenty-first.

Disappearance of icteric tinge in skin and conjunctivæ, mentioned in 21 returns, was complete in the average by the thirty-fifth day.

*Albuminuria.*—A note on the urine is made in 25 returns, information having been required as to the presence of albumin, casts, and spirochaetes. Albumin is definitely stated to be present in 12 cases, and casts in 5 of them. The remainder were returned as negative. As to spirochaetes there is no evidence that they were specially searched for except in E. G. P.'s returns, and he records a negative result in all the cases examined microscopically—i.e., 12, in 4 of which also inoculation of guinea-pigs was performed without effect.

#### *Note by E. G. P.*

This note is based upon 29 cases of jaundice under observation at a stationary hospital at the base during the months of August, September, and October, 1918. The cases were drawn from the front line, intermediate, and base areas.

They fell naturally into two divisions: 1. The catarrhal type, in which fever was entirely absent or very slight—that is, not over 100° F.—during the first few days of illness. Of these, there were 17, and in two cases only a record of any fever. 2. The pyrexial type, which again divided itself into two classes: (a) initial fever followed by a long-continued low grade of fever, in all seven cases; (b) initial fever, followed by a secondary rise of limited duration, five cases.

All the 29 cases fell within these divisions, and so far as is known there was no case which presented a high grade of initial fever which was not followed by the long-continued low grade of fever or by fever of a relapsing type. Of the 29 cases only two originated at the base itself, and these were of true catarrhal type. The others originated either in the front line itself or in the advanced lines of communication. Except for the two catarrhal cases mentioned above these cases did not arrive at the base until ten days or more had elapsed from the commencement of the illness, and therefore one had to depend upon the information to be obtained from the field cards or from the patients themselves, guided by the records on the field cards.

Although the pyrexial type is that which presents the most interesting features, it will be useful to give a description of the catarrhal cases, as it will serve as a useful contrast to the pyrexial cases, and will also be a record of catarrhal cases occurring in Northern Italy.

The *catarrhal cases*, then, were as a rule distinguished by a gradual onset, by absence of or only slight fever at the onset, by the tendency to early onset of jaundice, by the presence of clay-coloured stools, by the symptoms being mostly referable to the intestinal tract rather than generalised, by the rapid onset of convalescence after the disappearance of the jaundice, and by the absence of tachycardia as a sequela. The cases varied in severity from a very slight illness to one of a moderate grade of intensity. General symptoms, such as headache, dizziness, giddiness, pains in the back and limbs, cough, may be present, but they do not form the prominent features of the illness. These were referable to the intestinal tract and abdomen, and in addition to the jaundice consisted of loss of appetite, furring of the tongue, thirst, abdominal pains, nausea or vomiting, constipation or diarrhoea. Some abdominal pain was always present, but it varied very much in severity from the ordinary epigastric pain of indigestion and irregular gripping abdominal pains without abdominal tenderness to constant severe pain with distension and a general abdominal tenderness, but this latter was unusual. The position of the pain or tenderness in these cases is of importance, as only five of them referred it to the region of the gall-bladder or right costal margin, the others referring it to either the epigastrium or generally to the abdomen. In addition to the symptoms mentioned above, others occasionally noted were insomnia, general weakness, pains in the chest, drowsiness. One patient had a fine petechial rash on the chest and abdomen on the tenth day of illness, and one said that at the beginning of the illness there were streaks of blood in the vomit. None complained of itching of the skin and none had epistaxis or herpes.

The jaundice was characterised by a tendency to appear early in the course of the case. In the two cases which were local admissions the jaundice was present in both on the first day, but taking the whole 17 cases, in 11 the jaundice appeared during the first five days of the illness. The early onset of the jaundice was accompanied by a correspondingly early appearance of bile in the urine and disappearance of bile from the stools, these events generally showing themselves on the same day or the day after the appearance of the jaundice. The bile reappeared in the stools in two-thirds of the cases within two weeks, and in all within three weeks, of the onset of the illness. But disappearance of the bile from the urine was of later date, in two-thirds within three weeks and in all within four weeks.

The skin was normal in all but one within a month and was either coincident with, or followed in a few days, the disappearance of bile from the urine, but the conjunctivæ showed a tendency to remain coloured for a distinctly longer time than the skin, but only in one case for over a week.

In all the cases when bile was present in the urine albumin was also present, and in all when the bile disappeared the albumin also disappeared. In 2 cases casts were present in the urine; in one they were hyaline in character, in the other granular.

The spleen was enlarged to percussion in 9 cases, and in two of these instances was palpable. The liver was enlarged to percussion in 6 cases, but was never palpable.

The position of the apex beat of the heart was noted in every case, as it is of importance with relation to

on the sixth day of the illness. With the onset of jaundice there was a rapid decline of the fever, but although the patient generally felt better there was usually some drowsiness, apathy, very foul tongue, and had appetite, perhaps epistaxis or a petechial rash. The jaundice rapidly became very marked and very gradually died away, but bile was absent from the urine in all the cases at least three weeks before the fever entirely died away. With the disappearance of the jaundice the skin assumed the lemon tint, and anæmia was marked in all. The lemon tint made it

extremely difficult to say when the jaundice had really disappeared, as the two merged into one another. By the end of the second week the continued fever had generally started on its long and tedious course, during which it often stayed monotonously about 99° for some weeks. With regard to the abdominal conditions, the local symptoms did not compare in intensity with the more general ones, but the abdomen was usually tender, sometimes swollen, and the tenderness and pain showed a marked preference for the region of the gall-bladder and the right lower costal margin rather than the epigastrium. The condition of the bowels was at the onset of the illness either one of constipation or of diarrhoea, generally the former. One patient had herpes which developed on the sixth day with the jaundice, and one had swelling of the glands of the neck accompanying his sore-throat. Two had sore-throat which was of a severe character, but in neither was it the initial symptom. All the cases were extremely tedious in their convalescence, the fever not abating in the least severe until six weeks had elapsed from the beginning of the illness, and one had fever lasting ten weeks. After the fifth week there was a marked tendency to tachycardia.

There were five cases with the second type of pyrexia. Two of these presented the same sudden onset and symptoms as the first group. A short synopsis of their symptoms is appended. These two men belonged to the same battalion and were both stationed at Arzignano. The one was taken ill a day previous to the other. They were not companions, nor was there any apparent connexion between them in their duties. Their temperature charts show a remarkable similarity; the clinical picture of their cases was also similar.

enlargement of the liver, and in 5 of the cases where the liver was enlarged to percussion the apex heart was found in the fourth left interspace. The pulse-rate in 13 of the 17 cases was abnormally slow. Two cases showed reduplication of the heart sounds.

The examination of the stools showed in 3 cases out of the 17 the presence of the ova of *Trichocephalus dispar*, but as these ova were very commonly found in Italy in the stools of patients of all sorts, surgical and medical, it cannot be said that they should be regarded as a cause of the jaundice when present in this proportion.

One of the cases was a convalescent dysentery, and in another the jaundice appeared while the patient was in hospital suffering from a boil of the thigh.

All cases except one were convalescent within one month of the onset of the disease.

The pyrexial cases now claim our consideration, and they fall into two classes according to the type of fever. Those with: (1) an initial fever of about seven to ten days with an interval of five to seven days, in which the temperature remains about the normal, followed by a long-continued low grade of fever which lasts from about 30 to 60 days. (Chart 1.) (2) An initial fever of about seven to ten days with an interval of five to seven days, in which the temperature remains about the normal, followed by a secondary rise of about seven days' duration, and that again sometimes followed by a short tertiary rise, after which the temperature tends to settle to the normal in distinctly less time on the average than in the first class of case. (Chart 2.)

Of the 12 pyrexial cases, there were seven in the first class and five in the second class, and apart from the type of fever and perhaps a marked lemon tinge of the skin in the first class there was very little, if any, difference in the symptoms in the two classes, although in the second class there was not the same uniformity of severity as in the first.

The seven cases with a continued fever were all acute in onset, and the attack severe and prolonged. The symptoms were those which mark the onset of an acute pyrexial attack—viz., shivering and chill, high fever, sudden malaise, aching of the head, body, and limbs, thirst, marked weakness, sore-throat or injection of fauces, giddiness and dizziness, photophobia, suffusion of eyes, stiffness of neck muscles, accompanied by or followed in the course of a day or two by abdominal symptoms, pains in the stomach, vomiting, constipation or diarrhoea, jaundice appearing between the fourth and seventh days, commonly

CHART 1.—Pyrexial Type 1. Gr. P. Initial fever followed by long-continued low grade fever. This chart was continued to the 60th day, with irregular daily variations of temperature from normal to 99.8°.

CHART 2.—Pyrexial Type 2. Case 2, Pte. D. Initial fever followed by secondary rise of limited duration.

CASE 1.—Pte. L. Date of onset, 31.7.18. Onset very sudden, with sickness, diarrhoea, pains all over the body, headache and fever, pains in the stomach, and cough. 2.8.18: Jaundice and herpes. 5.8.18: Jaundice very marked, cough, headache, pains in the stomach. 11.8.18: Tongue very dirty, liver enlarged and tender, but not palpable. 14.8.18: Pain in the splenic region, with a fine friction over the spleen. No evidence of splenic enlargement. 26.9.18: Alveolar abscess. 29.9.18: Pleural friction at the right base, back and front, of a coarse character.

CASE 2.—Pte. D. Date of onset, 1.8.18. Onset very sudden, with pains in the head, fever, and shivering. 2.8.18: Slight epistaxis. 3.8.18: Haemoptysis and great weakness. 4.8.18: Temperature 104.2°; jaundice. 5.8.18: Jaundice marked and pains in the stomach. 6.8.18: Herpes of lips and left cheek. 11.8.18: Deep jaundice, erythematous and urticarial

rash of forearms, chest, and abdomen. Lower liver edge tender but not palpable. Spleen not enlarged. 13.8.18: Some small petechiæ in rash. 15.8.18: Rash almost disappeared. 16.8.18: Temperature 102.4°; apathetic. 19.8.18: Temperature 103.2°; vomiting and severe pains in the back; liver and spleen not enlarged. 23.8.18: Fever gone and patient rapidly improving in general condition.

Both showed a tendency to tachycardia after the fifth week.

The other three cases included in this group did not show the same severity of symptoms, and their fever was neither so high nor so prolonged, but they all had an initial fever followed by a secondary fever of limited duration.

The question then arises, Do these two groups of pyrexial cases own the same cause? As their symptoms are so much alike and their only difference appears to be the type of fever, it seems that this question must be answered in the affirmative.

Taking, then, these pyrexial cases as one group, in the 12 cases observed, the earliest appearance of jaundice was on the third day, in 2 the jaundice appeared on the fourth, and in the remainder between the fifth and tenth days, the commonest day being the sixth. Bile appeared in the urine shortly after the onset of the jaundice, but with regard to the stools there was nothing like the same constancy of disappearance of the bile from the stools, as in the catarrhal cases. Sometimes the stools were clay-coloured, but very often some amount of bile persisted in the stools throughout the illness. Bile was present in the urine in most instances up to the fourth or fifth week. Another feature with regard to the severe types was that the jaundice improved in spite of the persistence of the fever, and in most instances the temperature was still febrile after the bile had entirely disappeared from the urine.

The skin and conjunctivæ were not generally normal until the fifth to the eighth week, and the skin and conjunctivæ both seemed to approach to the normal at the same time, but owing to the lemon-tinted skin in the majority of cases it was difficult to say when the bile exactly disappeared from the skin. Casts were found in the urine in 5 cases out of the 12. In 1 hyaline, in 2 granular, and in the other 2 hyaline, granular, and epithelial. Epithelial casts were not found in the catarrhal forms. Albumin was present in the urine in all cases when bile was present. The spleen was enlarged to percussion in 5 cases, and in one of these it was palpable, this proportion not differing greatly from that found in the catarrhal cases. The liver was enlarged to percussion in 9 cases, in one of which it was palpable, the proportion here being much greater than in the catarrhal forms. The position of the apex beat of the heart was in the fourth space in 6 out of the 8 cases in which it was noted, and the liver was not enlarged in the 2 cases where it was in the normal position. The maximum point of pain or tenderness in the abdomen was in the position of the gall-bladder or under the right costal margin in 6 cases out of 11, in the epigastrium in 3, in the splenic region in 1, and in the left side of the abdomen in 1. This tendency for the pain to be situated in the right hypochondrium is doubtless in correlation with the greater proportion of cases of hepatic enlargement in these cases as compared with the catarrhal ones. The pulse-rate at the commencement of the illness seemed to vary, in some cases being slow in comparison with the temperature, in others commensurate with the fever, but with the onset of the jaundice it became abnormally slow in comparison with the fever, the lowest pulse-rate noted being 32.

The examination of the stools of these 12 cases disclosed the presence of the ova of parasitic worms in 6 of the 12, the ova of *Trichocephalus dispar* only in 3, the ova of *Ascaris lumbricoides* only in 1, the ova of *Trichocephalus dispar* and *ascaris* in 1, and the ova of *Trichocephalus dispar* and an adult *ascaris* in 1. As has been observed previously, these ova were quite commonly found amongst the troops in Italy, but the proportion found in these cases seemed to be above the average.

A blood count taken from Pte. D. on the seventeenth day of the disease during the secondary rise of temperature showed 4,096,000 red cells and 7000 white cells with nothing distinctive in the differential count. Blood pressure estimations showed nothing abnormal.

Five of the pyrexial cases were examined as to the presence of the enteric group of organisms in urine and faeces, three of the first group and two of the second. In all of these enteric group organisms were absent.

Blood cultures were taken from Pte. D. and Pte. L., the first being negative and the second showing a growth of *Staphylococcus aureus*, probably a contamination.

Investigations were undertaken as to the presence of the *Spirochaeta icterohaemorrhagiae*. In four of the cases, two of each group of the pyrexial types, a guinea-pig was inoculated but without result. All cases, both pyrexial and catarrhal, had a microscopical examination made of the urine, but the spirochaete was never found. Nevertheless, in spite of these negative results as to the presence of the spirochaete, it is felt that this may be a possible cause of the pyrexial cases, as they agree in their clinical character with the disease so well described by Dawson, Hume, and Bedson in their paper on spirochaetal jaundice, although they do not specifically describe cases with low continued fever. There were no deaths among these 29 cases.

*Conclusion.*—During the months of August, September, and October, 1918, there were prevalent amongst British troops in Northern Italy two types of jaundice—namely, catarrhal and pyrexial. The pyrexial cases again were subdivided into two groups, those with initial fever followed by a long low continued fever, and those with initial fever followed by a secondary fever of limited duration. These pyrexial cases apart from the temperature presented the same clinical features and showed a great resemblance to cases of spirochaetal jaundice, but there was no bacteriological evidence to support this view.

I must add my indebtedness to Lieutenant-Colonel C. Bramhall, R.A.M.C., for allowing these cases to be under my care, and to Major W. Broadbent, R.A.M.C., for his suggestions and interest in these cases.

#### *Concluding Remarks.*

We regret that by the force of circumstances the clinical facts in this communication are not supported by more bacteriological evidence. The bacteriological examinations were made by Captain W. Broughton-Alcock and Captain A. N. Smith, to whom we are much indebted, and whose technique is beyond question. The inoculations on guinea-pigs were made on the sixteenth, seventeenth, eighteenth, and twenty-seventh days of the disease, respectively, and therefore within the recognised limit of 28 days, but were all negative as to spirochaetal infection.

We are forced, therefore, to suspect that there may be some infection other than spirochaetal, though clinically similar to it, and that, if so, all these cases, with or without jaundice, may have this infection as a common causal factor. Nevertheless, we do not feel able to exclude dogmatically the spirochaetal factor, in spite of negative bacteriological results, in the face of the clinical resemblance of our cases to those published by the Japanese and British observers.

Although jaundice may occur as a complication of influenza, it is certainly not common in most civil epidemics, yet it is striking that in our first group these icteric cases should be so intimately associated in origin with, and so similar in their early symptomatology to, what seem to be "epidemic pyrexial" cases, and this circumstance gives an added interest to epidemic fever or influenza which raged in Italy from the early months and onwards of 1918.

We conclude with offering our thanks to the A.D.M.S., L. of C., Colonel Howell, for coöperation in obtaining returns, and the medical officers of all units for furnishing them.

**LIVINGSTONE COLLEGE.**—Dr. T. Jays, who has worked in different capacities with the Church Missionary Society and the Student Christian Movement, has become vice-principal at Livingstone College, and with his wife will reside in the College. In addition to helping the principal, Dr. Jays will take the lectures previously delivered by Colonel G. B. Price, who is now working with the Ministry of Pensions. Before the College reopens on Oct. 1st a short course of 15 lectures on Personal Care of Health in the Tropics will be given from Sept. 22nd–25th by the principal, vice-principal, and probably Colonel Price. These lectures are open to men and women, and are intended for those who expect to reside or travel in the tropics. They would be of use to missionaries, nurses, explorers, members of the services, Government officials, commercial men, &c. Application for terms and conditions of attendance should be made previous to the lectures to the Principal, Livingstone College, Leyton, E.10, who will be pleased to answer any questions with reference to these lectures or concerning the full nine months' course at Livingstone College, which will commence on Wednesday, Oct. 1st, 1919.

## THE EFFECTS OF ARTIFICIAL PNEUMOTHORAX.

By S. VERE PEARSON, M.D. CANTAB.,  
M.R.C.P. LOND.,

SENIOR RESIDENT PHYSICIAN, MUNDESLEY SANATORIUM.

THIS article is based upon the experience gained from 21 patients with severe pulmonary tuberculosis whose pneumothorax I induced artificially, except in one case (No. 19), between August, 1910, and December, 1916. The exception had developed a spontaneous hydro-pneumothorax which I converted into a controlled pneumothorax.

### *Striking Results of Artificial Pneumothorax.*

This series includes all those so treated by me during this period in whom the pneumothorax obtained was complete or nearly complete. Eleven of the 21 are alive, and all save two of these are enjoying good health and following their usual vocation.

No.	Sex and age.	Date of induction of pneumothorax.	Side.	Whether fluid present.	Whether fluid tapped.	Date of last (or latest) injection of gas.	Interval between most recent refills of gas.	Amount of gas taken at most recent refills.	Present state.
1	M., 34	13/8/10	R	+	+	Sept., 1911	4 w.	c.cm.	Died Jan., 1915.
2	M., 30	23/5/11	L	+	+	Feb., 1919	7 w.	600	Well; working.
3	M., 42	14/11/11	R	+	+	June, 1917	about 2 y.	350	Died July, 1918.
4	F., 22	20/11/11	L	+	+	Dec., 1912	2½ w.	180	Died March, 1913.
5	F., 17	1/1/12	R	-	-	Mar., 1914	6 w.	500	Died June, 1916.
6	F., 17	28/2/12	L	-	-	May, 1913	4 w.	700	Died Feb., 1915.
7	M., 24	13/1/13	L	+	+	Feb., 1915	6 w.	900	Well; working; about to marry.
8	M., 23	21/3/13	L	+	-	Feb., 1919	3½ m.	375	Well; working.
9	M., 34	7/7/13	R	+	+	May, 1917	2½ m.	400	"
10	M., 21	2/11/13	L	-	-	Feb., 1919	5 w.	1100	"
11	M., 38	5/11/13	R	-	-	Apr., 1914	2 w.	600	Died April, 1914.
12	F., 33	17/11/13	R	+	+	May, 1915	3 w.	120	Died August, 1915.
13	M., 35	3/1/14	R	-	-	Feb., 1914	10 d.	650	Died Feb., 1914.
14	M., 40	7/1/14	L	+	-	Jan., 1919	3 m.	900	Well; working.
15	F., 39	8/8/14	L	+	+	Feb., 1915	2 w.	200	Died March, 1915.
16	M., 46	8/9/14	R	+	+	May, 1918	12 m.	700	See below (a).
17	M., 26	2/12/14	L	-	-	Sept., 1918	2 m.	600	See below (b).
18	F., 21	4/6/15	R	+	+	Jan., 1919	6 w.	630	Well; working; married in 1918.
19	M., 53	28/4/16	R	+	-	Feb., 1918	1 m.	300	Died March, 1918.
20	M., 23	21/7/16	R	+	+	Feb., 1919	2 m.	500	Invalid.
21	F., 35	11/9/16	L	+	-	Dec., 1918	2½ m.	1000	Well; working.

y, years; m, months; w, weeks; d, days.

(a) Breathing apparatus good, but somewhat incapacitated by bone tuberculosis; (b) Fairly well, free from symptoms, but not capable of much work.

Nearly all of the ten who have died had their symptoms much alleviated and their lives materially prolonged, in several instances by years, during which they enjoyed fairly good health and followed their occupations. The restoration to health and activity of most of the 11 is wonderfully complete.

For example, No. 10 writes (January, 1919): "I have no trouble, enjoy good health, and I am quite unconscious of the fact that I am only using one lung. I feel a perfectly normal individual."

No. 7's doctor wrote (December, 1918): "He feels in perfect health. Can walk up hills better than his sister, who is a strong, healthy girl."

And No. 14, a doctor working regularly as a sanatorium physician for the past four years, now cycles occasionally 15 to 20 miles in a day, or does a quiet half day's shooting.

These results can justifiably be called remarkable when it is observed that they are obtained for people whose state was generally of such a nature that only a few months of serious invalidism could have been anticipated under the ordinary régime. The history of most of them is well exemplified by that of Nos. 2, 7, and 12.

No. 2 had been to two or three sanatoriums during the years before admission to Mundesley; he had had laryngeal as well as severe pulmonary lesions.

No. 7 had been under sanatorium treatment without avail in Devonshire and Mundesley for nearly two years before the induction of the pneumothorax, and had had serious symptoms for longer than this.

No. 12 had been ill for 3½ years before compression therapy was started; she had been unable to take exercise on account of fever for 15 months; she had half a mugful of muco-purulent expectoration containing tubercle bacilli.

Every case in the series had expectoration containing tubercle bacilli. But the nature and severity of the condition of these cases can be judged by reference to my previous writings on this subject.<sup>1</sup> The gist of the matter is that in nearly every case a situation had been reached which was quite hopeless apart from artificial pneumothorax.

A striking contrast to these results is to be found by following up the after-history of those patients for whom artificial pneumothorax was attempted unsuccessfully because of adhesions, including under this head those in whose cases pneumothorax treatment was abandoned at an early date because of the ineffectual, partial nature of the pneumothorax produced. During the same period (August, 1910, to December, 1916) I tried to induce a pneumothorax but failed completely on account of adhesions in six cases, and I induced only an ineffective, partial pneumothorax soon abandoned in seven other cases. All save one of these patients are dead. The one still alive does not enjoy good health and is unable to follow his occupation. The average length of life of the twelve who died, from the date of the attempt to induce a pneumothorax, was probably considerably under two years (I have not all the data for arriving at this average). Whereas the average length of life of those who died in spite of the artificial pneumothorax treatment was 2½ years, though the number includes 3 who only lived 1½, 4½, and 6 months respectively. And in the case of those with an effective pneumothorax who are still alive the average time to present date from the date of the induction of the artificial pneumothorax amounts to 4½ years, the longest time (No. 2) being 7½ years and the shortest (No. 21) 2½ years.

### *Factors affecting the Course of Treatment.*

In the rest of this article I shall deal with the results and complications of artificial pneumothorax as they affect the course of the treatment. As usual, difficulties, failures, and mistakes have taught me more in the course of the last 8½ years than all the routine management of those cases which have gone forward smoothly. As usual, too, in reviewing one's experience one finds that set rules are hard to lay down. Circumstances vary widely. Each factor at any particular juncture must be taken on its merits and weighed before a step is taken. But a few useful conclusions may be enunciated none the less.

(a) In the earlier stages of the treatment, say up to about 18 months, I believe there is greater likelihood of making a mistake by injecting gas too seldom and taking the pressures too high rather than erring in the opposite directions.

(b) I am convinced that abandonment of the injections of gas in a successful case after too short a period is a far worse error than the continuance of refills for too long. I believe No. 6 might have maintained perfectly good health had the treatment not been abandoned too soon, I may add, through no fault of the patient or of mine. About 18 months after starting the pneumothorax and about three months after stopping it, having been in apparent perfect health for nearly the whole of this time, she was looking upon herself as a perfectly normal individual, and was allowed to work eight hours a day studying at a college. Relapse set in about six months later, the pneumothorax could not be re-established, and the disease spread far. In the case of No. 5, too, whose subsequent history was somewhat similar, I am much inclined to think from subsequent experience that a further year of refills—i.e., 3½ years instead of 2½—might have produced a permanently good result.

<sup>1</sup> E.g., to articles in *The Practitioner* (September, 1911) on "The Choice of the Patient for Artificial Pneumothorax," and in the *British Medical Journal* (Oct. 12th, 1912), where further details and a more ample history of several of the patients can be found. In the present series, Nos. 1 and 2 are Nos. 1 and 4 in the first article, and Nos. 3, 4, 5, and 6 are Nos. 3, 2, 4, and 5, respectively, in the second paper.

(c) It is by no means an invariable rule for the pleural surfaces to become adherent after injections have been given up. A patient not included in this series because not originally "blown up" by me consulted me five years ago. It was decided to attempt to give an injection of gas, though no refill had been given for just over two years. Rather to our surprise several hundred c.cm. of nitrogen were injected without difficulty. This patient's artificial pneumothorax was started abroad ten years ago. He has been earning his living for the last 8½ years. Again, No. 2 in this series once went about 15 months without a refill. He then met with a street accident, and a few weeks later, feeling uncomfortable, consulted me. I withdrew two and a half pints of deeply blood-stained fluid from his left chest and gave 1400 c.cm. of nitrogen. This was on April 24th, 1915. Since then he has continued to have occasional refills, because he felt better with them than during the many months of their abandonment. No. 3, too, once went two years between injections, but then he had an appreciable amount of fluid in the chest probably throughout this time. I shall make further reference to his case below.

(d) Every endeavour should be made to keep the pneumothorax cavity always a closed one. The only excuse for disregard of this rule seems to me to be the presence of secondary micro-organisms. In none of my cases has this happened. In passing I may mention that after careful search tubercle bacilli can be found in the purulent sediment from the fluid in many of these cases, I should think in about 75 per cent. of those with fluid. If once a tube is put into a tuberculous pyothorax cavity the chances are that a permanent sinus persists, requiring all the bother of dressings at least once a day, and bringing every likelihood of secondary infection, however much care is taken to avoid it. Case No. 1 suffered from at least one of these disabilities for several years, and they might in all probability have been avoided.

(e) Those cases which develop fluid at any time in the course of the treatment want watching with special care. It is amongst these patients that sequelæ requiring careful handling are particularly likely to occur. Under this head there are many important points, and they demand several paragraphs. But before dealing with them I will describe briefly some other peculiarities which are met in the later periods of the treatment, say after the second year. These can be classified under the heads of anatomical and physiological.

#### *Anatomical Considerations.*

It is surprising how small the visible deformity of the chest is in these cases. Little difference is observable on casual inspection, sometimes only very slight inclination to the "barrel-shaped" type of thorax, and to diminished movement on one side. Case No. 7 was passed for military service in August, 1914, only to have his schemes thwarted by his practitioner. But in 1915 he attested under the Derby scheme and was passed Class A.

None the less in many cases the ribs come very close together by degrees, and in most the inflated side of the thorax comes to be partly filled by much displaced mediastinal and subdiaphragmatic organs. On the left side, e.g., the heart may come to be quite 3 in. outside the nipple line and displaced upwards considerably as well, while the stomach comes quite high in the chest. My impression is that great displacements are commoner on the left side than on the right. Occasionally the mobility of the mediastinum and its contents, which varies in different individuals, is largely lost, and the heart becomes more or less anchored, displaced to the side with the compressed lung. But more frequently the displacement is altered in amount by a refill, even years after the starting of the pneumothorax. Seldom, however, does a refill really late in the course of the treatment lead to any considerable displacement of organs away from the side of the compressed lung.

Considerable thickening of the pleura, especially of the parietal pleura, occurs in a moderate number of patients by about the third year. The practised hand can usually feel and gauge this at the time when the needle is inserted for a refill, and the golden rule must be observed of never giving any gas unless the appropriate oscillations are present. My needle once got into the pericardium, and I found well-marked negative oscillations, but synchronous with the heart beat. Naturally I withdrew the needle, afterwards giving an ordinary refill. There was no untoward result.

On another occasion, on introducing the needle rather deeply to get through a thick pleura in a high position rather far back in the axilla of a patient who had been having refills for several years at three-monthly intervals, a soft sibilant squeak was audible at the very end of each inspiration referred to the chest by the patient. The pressure, as shown by the manometer, was much below zero, but the oscillations were not free. When I withdrew the needle a little the squeak stopped, the negative pressure became more pronounced, and the oscillations much greater. I concluded I had wounded the lung a trifle. An ordinary refill took place and no adverse symptom whatsoever arose.

#### *Physiological Peculiarities.*

Under the head of physiological peculiarities, belonging more especially to the late stages of the treatment, the low pressure readings are important, because before starting the refill of gas preparations for the low negative pressures must be made. These are, of course, prone to occur, especially when the intervals between refills are long—two or more months. Under such circumstances it is necessary to see that there are about 7 to 10 cm. or more for some cases of a negative pressure in the gas bottle just before starting, and to take care that the bulb at the top of the negative stem of the manometer is large enough—a state of affairs not, I fear, usually to be found in the apparatus hailing from the instrument-makers. As an illustration of such readings (when below -34 approximate only) I append the following from Case 14:—

Date of refill.	Starting pressures.	Amount of gas given.	Ending pressures.
25/8/17	-32 -12	800	-8 -2
29/11/17	-44 -20	925	-13 -6
22/2/18	-42 -22	800	-13 -6
27/4/18	-40 -16	930	-9 -5

Another fairly common physiological peculiarity worth mentioning, a fortunate one, but one which needs vigilance and guardianship, is the restoration to health of a person accustomed to severe illness, possibly for years. He may on this account be disinclined to continue the refills of gas for a reasonable time; and he may get careless about his health. Such carelessness, in accordance with all the general principles applicable to such a class of case, simply courts relapse, disaster, and death. In this connexion, too, those who absorb the gas comparatively quickly should be especially cautious to refer regularly, at not too long intervals, to their doctors, lest undesired premature re-expansion of the lung accompanied by adherence of its surface set in through leading too strenuous a life. At the other extreme amongst the restored is to be found occasionally one who is over-reluctant to abandon the refills, or to reduce their frequency to a sufficient moderation. But, as I have already indicated, this is an error on the safe side.

#### *The Presence of Fluid.*

Now with regard to cases in which fluid arises, and it must be borne in mind that this includes about 70 per cent. of all cases, the course of the treatment is nearly always rather more complicated than when there is no fluid. Not invariably though, because sometimes effusion occurs and then dries up again spontaneously without disturbing events materially. Even in such circumstances, however, there is commonly some interference with the spacing of the injections of gas. But this subject has been fairly adequately dealt with in the previous literature on artificial pneumothorax, so I will pass on to further points. In reference to the incidence of fluid in these cases (see above table) two points must be observed, viz: The + sign indicates the presence of fluid in the course of the treatment, extending over years in many cases, even when the amount of the fluid has been small, and its interference with the health and comfort of the patient inappreciable. Secondly, the + sign in the next column may mean only one aspiration or several.

Occasionally it may happen that it is a little difficult to distinguish between fluid in the stomach and in the chest, more particularly on the left side, of course. It must be remembered that the stomach gets into a high position, and that some patients are apt to anticipate a pleural splash. I

have had three or four doctors amongst these patients, and one of these even raised the question, quite justifiably, as to whether a curious little flapping splash was not due to pericardial fluid. The occurrence of this splash only bothered the patient in one position and it synchronised with the heart beat. But we were able by careful examination, though not quite easily, to localise the fluid to a displaced and slightly dilated stomach. When fluid was present in this organ and a certain position was taken up the heart jogged it and a slight splash reverberated through there being a sounding-box, so to speak, just above it in the shape of a small, old-established pneumothorax cavity. It is usually quite easy to localise the fluid by means of percussion, x ray examination, to a small extent by the sensations of the patient, and especially by noticing the peculiarly metallic, ringing nature of the splash when the fluid is within the chest as compared with its duller resonance to the ear, applied by stethoscope or held close to the patient when shaken, if the fluid is only a stomach splash.

*Cases Illustrating Points in Relation to Presence of Fluid.*

A partial account of events in the cases of two patients (Nos. 3 and 12) will best serve to bring out certain other difficulties and pitfalls connected with the presence of fluid during the late stages of the treatment.

First, a few facts regarding fluid withdrawals in Case No. 3. But these do not include all such facts about him, as during the course of his 7½ years of life after the first "blowing up" he consulted many physicians at home and abroad, and on one or two occasions other than those noted here I believe he had fluid withdrawn and replaced by gas.

Date.	Pressures.		Fluid withdrawn.	Gas given.	Ending pressures.
	At starting.	During operation.			
27.3.12	+ 3 + 6	...	c.cm. 400	...	...
3.4.12	...	...	2420	2600	+18 +23
18.5.12	+10 +15	...	475	800	+ 6 +12
12.9.12	...	-16 -20	3650	1200	- 4 + 1
4.12.12	0 + 6	...	...	125	+ 8 +13

8.6.17	...	...	550‡	...	...

\* After ½ pint of fluid had been withdrawn.

† After 550 c.cm. of fluid had been withdrawn.

‡ After much pus had been coughed up.

I should mention incidentally that this patient did not lead a very invalid life most of the 7½ years. He held a prominent place both in public life and in the business world. Though in 1912 he returned for a time to his public duties he wisely gave these up after a few months. He maintained the supervision of his big business and of his private concerns fairly intimately until about 14 months before his death, though taking a few months' holiday every now and then, and generally spending such periods in a sanatorium in England or abroad. I believe his death was accelerated by the complications which arose in connexion with the fluid in the right chest. During 1915 and 1916, when on the continent, he consulted one or two prominent foreign specialists—i.e., Professor Saugmann—at whose sanatorium he stayed for a short time, and Dr. L. Spengler. They advised leaving the fluid alone as it appeared to have become limited, stationary in amount, and turbid in consistence. When I saw the patient again after a long interval at the end of December, 1916, I concurred in this view, though finding considerable dullness, &c. I ascribed some of the dullness to thickened pleura. The patient stopped rather over two months in the Mundesley Sanatorium at this juncture, and left in a fairly good state. About two months later he became feverish and ill, and on readmission on May 25th, 1917, his state was unsatisfactory. The upper half of the right lung presented signs at first taken by myself and colleague for massive consolidation. Over the front of the fifth rib anteriorly was a swelling mistaken at first for a cold abscess connected with tuberculous disease of the rib. Sub-

sequently the true state of affairs, a pyothorax pointing anteriorly, was diagnosed, but not until early June. The withdrawal of 550 c.cm. of fluid on May 31st had been deceptive. Dr. M. F. Squire, my assistant, and I thought we had got most of the semi-purulent fluid out; but we had not, evidently being balked by its flakiness, though we did use a fairly large aspirating needle. Again, we probably made a mistake in raising the pressures to a maximum of + 25 cm. of water on June 6th. Unfortunately, our plans for a further and, if possible, a complete aspiration of fluid, were anticipated by an hour by the bursting of the pyothorax internally through the lung. The withdrawal after this of what fluid we could get out by aspiration, in the hope of the hole in the lung healing, was of no avail. Later, on account of the weakening effects of distressing cough and copious purulent expectoration, it seemed best to introduce a tube. This was accordingly done on August 7th, 1917, by Mr. Lawrie McGavin under copious injection of a local anæsthetic. The general condition of the patient, and the, by this time, moderate tuberculous infiltration of the left lung, put a general anæsthetic out of court. The operation was well stood and did much good, and the patient was able to get about a little for a good many months.

The history of Case 12 is very similar to the case just described. She first developed fluid one year after the initial injection (given Nov. 17th, 1913). It was first tapped six months later—namely, on June 5th, 1914. After about three tapplings during the next nine months it had become turbid and seemed to show no great inclination to reaccumulate. The ribs got very close together. Restoration of health, though gratifying for a time, never became complete, and about May, 1915, the disease in the sounder left lung had advanced a good deal. Difficulties arose in maintaining the pneumothorax and in regard to the fluid. These difficulties were due to incomplete collapse and re-expansion of the lung with formation of adhesions at the top of the chest posteriorly, to the turbidity of the fluid and the purulent flakes in it, and to the great proximity of the ribs in the only region where it was convenient and suitable to try to inject gas. These difficulties, combined with the other circumstances of the case at this juncture, decided Dr. C. Lillingston, under whose care the patient then was, in consultation with myself, to abandon further attempts at injecting gas or withdrawing fluid. This decision was arrived at on June 1st, 1915. Three months later the patient had a sudden severe fit of coughing and every indication that the fluid in the pleural cavity had burst through into the lung. She died a few days later. In the middle of the previous April I had made the following note in the form of a question:—

"How far is each of the following factors responsible for the present unsatisfactory condition: (1) Activity of disease in the sounder lung; (2) activity of disease in uncompressed part of the right lung; and (3) pleurisy and fluid on compressed side?" I have no doubt now that I underestimated the third factor, and that had we made a bold and successful effort to withdraw fluid again and replace by gas the condition of the patient would have been bettered and in all probability her life prolonged.

*Further Points in Regard to Fluid.*

Besides the lessons already indicated in the course of describing the events which occurred to these two patients one or two further morals can be drawn from experience with these and other patients. Fluid generally, especially in the early stages of the treatment, tends to keep intrapleural pressures up. It is more likely to be followed by thickened pleura and adhesions, possibly sudden ones, than when there is no fluid. Hence, it is customary to keep pressures rather higher in such cases than in those not developing fluid, particularly because a moderate degree of pressure is thought to keep fluid from accumulating too readily. It is a good rule not to interfere with fluid unless obliged to through the chest becoming very full or for some similar reason. But both these rules can be followed too closely in the late stages of the treatment. In such stages—e.g., during the fourth year after the initial induction—in cases of fluid where an effective pneumothorax has been produced, it is as well sometimes not to be too readily deterred from continuing the treatment by such difficulties as fluid getting into the gas needle or pus flakes into the fluid needle. The remedy for each of these troubles is obvious—namely, withdrawal of fluid and reduction of

pleural pressures thereby before attempting to give a refill of gas in the one case, and the use of a larger bored needle or trocar and cannula for aspiration in the other. In connexion, however, with the latter means of overcoming difficulty in withdrawal of fluid, the possibility of leaving a sinus must be mentioned: to be avoided by preventing too big an accumulation of fluid and too high a pressure, and by appropriate manipulation of the skin and of the insertion and extraction of the instrument. Local anæsthesia is helpful and generally advisable for fluid aspiration. With its aid chest punctures need not be too charily undertaken.

One further point in connexion with fluid is illustrated by reference to Case 14, some of whose pressure readings at refills in the fourth year of treatment are given above as an example of low pressures. In this case no fluid arose until April, 1917—i.e., 39 months from the commencement of treatment—by which time the intervals between refills extended to seven weeks, and minimum pressures of  $-18$  and  $-24$  were found just before beginning an injection. At no time since then has fluid had to be withdrawn, nor has it become in any way more than a trifling nuisance. It seems obvious that in this case fluid has arisen in response to nature's abhorrence of a vacuum. Since the lung in his case, as sometimes happens, shows little inclination to re-expand, the obvious course of treatment is to give an occasional dose of gas to meet nature's demands in a more comfortable, controllable, safe, and convenient manner than is done by the effusion of fluid.

#### *Indications for Cessation of Treatment: Spacing of Doses.*

This leads me to one or two final matters for consideration, the most important of which is: What are the indications for stopping the treatment? If I myself had to have resort to an artificial pneumothorax I should like to have it kept up for at least three years, provided it was an effective one and this was possible. And under the three following circumstances I advise continuing with an occasional injection for at least  $4\frac{1}{2}$  years—namely (1) if the patient is over 33 years and has lost the resilience and recuperative powers of youth; (2) if the compressed lung was a fairly useless one before the initial injection, and if, in addition, it was producing chronic poisoning; and (3) if things are going well during the maintenance of the compression.

Compression may have to be maintained indefinitely—e.g., in Cases 2, 8, 10, and 14—either because the patient's state is more comfortable and he feels surer of himself with periodic refills, or because the compressed lung does not re-expand. On the other hand, compression with an effective pneumothorax may have to be abandoned prematurely because of activity of disease in the sounder lung or because of re-expansion of the compressed lung and adhesions. But in the first case most probably this is due to an error in the choice of the patient for this method of treatment, and in the second case most probably carelessness in not watching the patient and giving refills sufficiently often is the cause of re-expansion and adhesions.

Occasionally the treatment has to be abandoned after a long time, because a day comes when it is found very difficult, or even impossible, to continue it. In giving details above about Case 12 I have indicated the sort of combination of circumstance which may lead to this, though admitting that in this particular case we were too easily deterred from persevering by the difficulties encountered. But more usually, if the pneumothorax cavity cannot be found, it is in the case of a patient in good health who has been having treatment for four or five years; under such circumstances it does not matter much. It is better, however, to choose the time of leaving off injections voluntarily by persuading the patient not to let too long elapse before he sees his doctor about his condition and about a possible refill.

No hard-and-fast rules can be laid down respecting the spacing of doses in the late stages of the treatment, nor respecting the pressures. Compare, for example, Case 10 with Case 8. No. 10, whose present satisfactory condition I have already referred to, does not like to let his pressures go below a minimum of  $-14$  or thereabouts, nor to prolong the interval appreciably beyond five weeks. Whereas No. 8, starting a pneumothorax only about seven months earlier—namely, in March, 1913—is quite happy to allow four months between refills; his pressures do not fall much below No. 10's, however, and probably this slower absorption accounts for the difference between them. Both lead quite active and more or less normal lives.

#### *Causes of Death.*

One or two more notes giving a few further details of interest regarding the patients of this series seem desirable. Most of those who died succumbed to the advance of the pulmonary tuberculosis. In Case 11 death took place six hours after a refill, and may possibly afford an exception to the rule holding good throughout this series, comprising many hundreds of injections—namely, that no unfortunate effect ever arises from injecting gas into the thorax when the necessary simple precautions are taken. This patient felt perfectly all right for two hours after his refill. He dressed and came down to dinner, when he was seized with sudden dyspnoea. This was not relieved by letting gas out again, a procedure which revealed the fact that no hole in the compressed lung had developed. Suspicions fell on a spontaneous pneumothorax on the opposite side of the chest, the occurrence of which accident accounted for death in Case 19. Unfortunately, no necropsy was possible. In Case 13 the condition was of South African mining origin, and this probably augmented its hopelessness. No. 15 died of tuberculous meningitis. No. 9 nearly died some months after the induction of the artificial pneumothorax, but eventually his health became well restored. Once he got for a few days disconcerting mediastinal interstitial emphysema—the only instance I have experienced of this complication.

In conclusion, I may mention that the following physicians, amongst others, have aided me with their advice or have participated in the treatment at some juncture or other in the course of events in one or more of the cases in this series, and I herewith acknowledge their help with much gratitude: A. Latham, T. D. Lister, Hector Mackenzie, J. J. Perkins, A. G. Phear, Clive Riviere, Jane Walker, R. A. Young, F. W. Burton-Fanning, C. Lillingston, John Hay, A. C. Inman, A. de W. Snowden, A. Lewthwaite, M. F. Squire, L. Whittaker Sharp, Esther Carling, E. G. Colville, C. V. Knight, H. H. Brown, and J. D. McKelvie.

## OUTBREAKS OF CEREBRO-SPINAL FEVER IN RELATION TO ATMOSPHERIC HUMIDITY:

INFLUENCE OF THE HUMIDITY OF OVERCROWDING.

BY ARTHUR COMPTON, M.B., B.CH. (R.U.I.), D.Sc. (N.U.I.)

EX-CAPTAIN, R.A.M.C.; LATE OFFICER COMMANDING NO. 32 MOBILE  
BACTERIOLOGICAL LABORATORY, E.E.F.; FORMERLY OFFICER  
IN CHARGE, MILITARY BACTERIOLOGICAL LABORATORY,  
DORSET DISTRICT.

CEREBRO-SPINAL fever, as a disease, being supposed to be comparatively rare in Egypt, some investigation of the question appeared desirable in view of obtaining if confirmed helpful sidelights on prevention for our own more temperate climate.

Moreover, having as the result of previous work<sup>1</sup> in the Dorset District (England) developed the hypothesis that: atmospheric humidity—more especially indoor humidity,<sup>2</sup> operating through overcrowding and insufficient ventilation—was a climatic factor which favoured outbreaks of the disease, when the meningococcus was about, it became important to test this hypothesis for a country like Egypt, where at times a very moist atmosphere prevails.<sup>3</sup> If the observation in regard to comparative rarity of the disease in that country were exact, and our humidity hypothesis otherwise stood unassailed, the explanation could practically a priori only be: comparative absence of the meningococcus in Egypt. And that explanation appeared the more probable in view of the abundant sunshine of Egypt: it being well known that "carrier rates" in England are lowest during summer months, when sunshine is at its maximum.

#### *Scope of Investigation.*

To test these various ideas was the principal object of the work with which this paper deals, and for the purpose of

<sup>1</sup> Arthur Compton: Jour. R.A.M.C., November, 1915, 546-570; Comptes rendus, 1915, cli., 472; THE LANCET, 1916, i., 255.

<sup>2</sup> Arthur Compton: Third Report to the War Office on C.S.F. in the Dorset District, Nov. 1st, 1917 (not yet published).

<sup>3</sup> "Alexandria ..... is quite unsuited as a residence for invalids, its climate being damp and windy; and under these circumstances alternations of heat and cold are extremely trying." Huggard: A Handbook of Climatic Treatment, London, 1906, 189.

the investigation use has been made of a small outbreak of the disease, some 10 cases in all, which occurred in the Alexandria District, E.E.F., during February and March, 1918, just prior to my arrival in Egypt.

In the necessarily brief investigation which it was possible for me to make, for I was limited by military necessity to a three weeks' time-limit, four main points were set out to be investigated: (1) To what extent the Alexandria District was affected by the disease (Studies in Statistics); (2) the relation of the cases in the above-mentioned outbreak to atmospheric humidity (Studies in Outdoor Humidity); (3) to what degree humidity was high indoors—evidence of "overcrowding" and insufficient ventilation—in the sleeping quarters where the cases had occurred (Studies in Ventilation); (4) to what extent the meningococcus was about (Studies in "Carrier rates").

For the investigation I am indebted to Lieutenant-Colonel M. H. Gordon, R.A.M.C., and Major T. G. M. Hine, R.A.M.C., for a small supply of Central Laboratory medium (pea-flour-agar and serum), agglutinating sera of the four defined epidemiological types of meningococci, and West's naso-pharyngeal swabs. In all respects, therefore, the work was comparable, in so far as medium and technique<sup>4</sup> were concerned, with previous work in England.

#### Statistical Study.

Table I. gives the number of cases (military) of the disease occurring in the Alexandria District for the three years 1915-16, 1916-17, and 1917-18, as compiled from the official "weekly returns" in the A.D.M.S. Office, Alexandria; and for comparison I have given the corresponding numbers dealt with by the Dorset District Military Bacteriological Laboratory during the same periods, the military populations of both areas being approximately the same.

A glance at Table I. reveals that the disease has been rarer in the Alexandria District (Egypt) in the proportion of  $40/117=1/2.9=1/3$  approx., as compared with the Dorset District (England), for the three years in question. The

TABLE I.—Cases of Cerebro-spinal Fever.

Year.	Alexandria District (Egypt).	Dorset District (England).
July, 1915-June, 1916 ... ..	22 cases.	55 cases.
July, 1916-June, 1917 ... ..	3 "	49 "
July, 1917-June, 1918 ... ..	15 "	13 "
—	40 "	117 "

observation, therefore, in regard to comparative rarity of the disease in Egypt would, from this analysis, appear to be more or less borne out. But, although this is so, it is evident that Egypt is far from being exempt from the disease.

When the Alexandria District numbers are rearranged in terms of station (camps, hospitals, &c.) the above table becomes instructive. This has been done in Table II.

TABLE II.—Incidence at Various Stations.

Year.	Sidi Bishr.	Mex.	Metras.	Mustapha.	Aboukir.	"A" Camp.	Transports and hospital ships.	Hospitals.
1915-1916 ...	3	9	1	—	—	—	4	2
1916-1917 ...	1	—	1	1	—	—	—	—
1917-1918 ...	—	10	—	1	1	2	—	1

Table II. shows that Mex Camp is the centre in the area which has given rise to most cases of the disease, except that in 1916-17 it entirely escaped. But, as will already

have been noticed in Table I., during that year only three cases in all are recorded as having occurred in the area. Whether it may afford an explanation or not, it is interesting to note that during eight weeks (July 2nd till August 28th) Mex Camp was quite unoccupied. This camp is ordinarily occupied by British West India troops, among whom during February and March, 1918, the 10 cases of 1917-1918 (Table II.) occurred. It is with these 10 cases that this investigation primarily deals.

#### Studies in Out-door Humidity.

Of the 10 Mex Camp cases of February and March, 1918, Fig. 1 gives their approximate distribution on an "out-of-doors" 8 A.M. Alexandria humidity chart (from the meteorological readings of Mr. H. Sherif, Kom-el-Nadura Observatory).

As it has not been possible to ascertain the exact date of onset of the disease for these cases (see Appendix), this has had to be allowed for. The position of each name on the chart (Fig. 1) is, therefore, that of the day before the date given in official records when the patient was admitted to

FIG. 1.—Distribution of the 10 Mex Camp cases of cerebro-spinal fever shown on an out-of-doors percentage humidity chart.

hospital. Considering an out-of-doors relative humidity of over 75 per cent. as constituting a moist atmosphere, it will be seen that the cases practically all occur in connexion with periods when such a standard out-of-doors was exceeded. What it was indoors in the men's tents, where presumably they took ill—which is what we should like to know—is not revealed by Fig. 1, but some idea of what it probably was, will appear presently, when Fig. 2 comes to be studied. Suffice it in passing, then, to note that this small outbreak at Mex Camp, Alexandria, in no way conflicts with, but, on the contrary, fully bears out, our hypothesis connecting the disease with a high degree of atmospheric humidity.

#### Indoor Humidity and Ventilation Studies.

Having previously shown that indoor relative humidity readings taken at "lights out" and at "réveillé," compared with outdoor morning readings, may be utilised as a simple method<sup>2</sup>—which, so far as I am aware, is original—to gauge the efficiency, or otherwise, of ventilation in sleeping-quarters, from the point of view of overcrowding, I have had such readings taken from a particular tent at Mex Camp pointed out to me as where several of the recent cases had taken ill. As suitable controls, corresponding readings were taken simultaneously in a tent and in a hut at No. 21 General Hospital, Alexandria.

That overcrowding and insufficient ventilation, as evidenced by their effects on indoor humidity, may be the better appreciated in what follows, the following additional details in regard to these three sites where hygrometers were installed will be of interest:—

(1) Tent Mex Camp. "Bell" model, of approximately 600 c.ft. capacity in D Co. "lines," 5 men of the British West India Regiment occupying the tent during the investigation.

(2) Tent No. 21 General Hospital. "Bell" model, of the same capacity, occupied during the investigation by 5 R.A.M.C. orderlies, but presumably better ventilated in that the flaps of the tent were always kept well open at night.

<sup>4</sup> See War Office Memorandum on Cerebro spinal Fever. 24 Gen. No. 3595 A.M.D. 2.

(3) Hut No. 21 General Hospital. Hut No. 9 officers' quarters, of approximately 2000 c.ft. capacity (22 x 10 x 9), occupied by one person, the hut having two windows facing the sea practically always open.

Fig. 2.—Giving a graphic representation of percentage relative humidity in three neighbouring quarters, for the same period.

Fig. 2 gives the graphical representations of the readings taken in the quarters (1), (2), and (3) respectively. To estimate the efficiency, or otherwise, of ventilation from such graphs, the following differential table (No. III.), which is a résumé of data established by us in a previous work,<sup>2</sup> will be required for reference.

TABLE III.

GOOD VENTILATION.		BAD VENTILATION.	
1. Relative Positions of the Three Curves.			
"Morning out-of-doors" highest, "réveillé" intermediate, "lights out" lowest.		"Réveillé" highest, "lights out" intermediate, "morning out-of-doors" lowest.	
2. Displacement Between the "Réveillé" and "Lights Out" Curves.			
The displacement is usually small, the two curves being, as it were, packed together throughout their course.		The two curves are more or less widely separated.	
3. Relation of the "Réveillé" Curve to the Other Two.			
Its position being intermediate to the other two it generally follows a course related to them more or less mathematically as a mean to two extremes.		Rising to a higher level than the other two, being often situated in the region of complete saturation, it follows a more or less independent course.	
4. Relation of the "Morning Out-of-doors" Curve to the Other Two.			
In good ventilation the other two curves being relatively lower, while the "morning out-of-doors" curve is in a sense constant, causes the latter curve to appear comparatively higher: as, indeed, it usually is actually.		In bad ventilation the other two curves being relatively higher causes the level of the "morning out-of-doors" curve to appear comparatively much lower.	

Judged by the criteria of Table III., it will be seen that the curves appertaining to the hut (No. 21 General Hospital) portray a better ventilation than those of the tent (No. 21 General Hospital), and these latter a better ventilation than those of the tent (Mex Camp). In other words, the ventilation in the B.W.I. tent at Mex Camp is shown to be worse than that of the R.A.M.C. orderlies' tent at the No. 21 General Hospital, and that of the officers' hut at No. 21 General Hospital best of all. The importance of this finding will be evident. It points, I think, to insufficiency of ventilation, to deal with the excessive indoor humidity consecutive on the overcrowding present in the Mex tent, as responsible for the outbreak in that camp of February and March, 1918, the meningococcus being about. Indeed, as the "réveillé" curve for Mex Camp (see top diagram, Fig. 2) indicates, as a rule, a high morning humidity bordering on saturation—between 80 and 100 per cent.—it will be obvious, on our humidity hypothesis, that a "carrier" sleeping in such a tent would run a greater risk of developing the disease than if he slept in a tent of the No. 21 General Hospital standard of ventilation and humidity; for, theoretically, as has been emphasised by me elsewhere,<sup>5</sup> good ventilation, by counter-acting the effects of indoor humidity, means diminished risk of the "carrier" infecting his comrades and of the "carrier" himself becoming a case.

Studies in "Carrier Rates."<sup>6</sup>

The object in view being to determine to what extent the meningococcus was about, as many men were swabbed in the district as it was possible to handle with the small supply of special medium at disposal and the limited time available. Some 310 non-contacts (from Mex and Mustapha Camps, and Nos. 19 and 21 General Hospitals) were thus swabbed; also, some 24 direct and indirect "contacts" of an actual case, Pte. G. (see Appendix), readmitted to hospital as a case of relapse on April 25th at the time this investigation was in progress.

From two lumbar punctures of April 25th and 26th respectively, a Type III. (Gordon) meningococcus was grown from the cerebro-spinal fluid of the case (G.) showing perfect agglutination up to a serum dilution of 1:400 after 24 hours at 55° C., being quite untouched by Types I., II., and IV. sera.

Contacts.—Of the above case (G.) there were 8 contacts who had inhabited the same marquee with him during two days (April 23rd to 25th) at Mustapha Camp. These were swabbed on April 26th, and all gave negative results. In addition, there were at Mex Camp 5 men who were doubtful contacts, in the sense that they had been in contact with G. some time previously, and 11 other men who had been in contact with these 5. The 16 were swabbed on April 27th; 15 were negative, and 1 gave a meningococcus-like organism, which subsequently by the agglutination test proved to be non-agglutinable and was reported as negative.

It is not without interest that one of the five Mustapha contacts, Pte. B., was a recovered case, having had the disease in February, 1918 (see Appendix).

(A) Number giving meningococcus-like organisms (cult. app. and micros. app.).

(B) Number giving epidemiological meningococci (Gordon)—i.e., meningococcus-like organisms agglutinated by one of the four types of antisera.

<sup>5</sup> Arthur Compton: Comptes rendus, 1917, clxv., 75; Ann. Inst. Past., 1918, xxxii., 130.

<sup>6</sup> I desire here to thank Staff-Sergeant J.W.J. Leighton, B.Sc. Lond., R.A.M.C. (T.), for his valuable assistance in this work.

*Non-contacts.*—Table IV. summarises the findings with regard to the naso-pharyngeal swabs taken from non-contacts at various centres in the district. The 3 "agglutinable" meningococci found all belonged to Type II. strain; and while 1 agglutinated up to a dilution of 1:400, the remaining 2 only agglutinated up to a dilution of 1:100. Of the 19 meningococcus-like organisms met with in the naso-pharynx during the course of the investigation, the fermentation reactions of 10 of them which survived subculture were determined; as also those of the meningococcus G. isolated from the cerebro-spinal fluid. Table V. gives a summary of these fermentation tests:—

TABLE V.

Lab. No.	If agglutinable. Type.	Fermentation reactions.			Lab. No.	If agglutinable. Type.	Fermentation reactions.		
		Gluc.	Malt.	Sacc.			Gluc.	Malt.	Sacc.

116	—	+	+	—	328	—	+	+	—
140	II.	+	+	—	G.	III.	+	+	—
158	—	+	+	—					

Gluc., glucose. Malt., maltose. Sacc., saccharose.

As will be seen, both the epidemiological ("agglutinable") and the other ("non-agglutinable") meningococci found during the course of the investigation all give the same fermentation reactions. This corresponds with previous experience.

As a practical Army measure, however, only "agglutinable" meningococci are recognised as constituting true "carriers." This is based on the teaching of the Central Cerebro-Spinal Fever Laboratory, London, which holds that only men harbouring meningococci agglutinating with standard type sera up to a dilution of at least 1:200, after 24 hours at 55°C., as against controls, are to be considered as constituting an immediate source of danger. Meningococci from cerebro-spinal fluids show agglutination up to this titre and, as a rule, beyond.

In the present investigation, in order to standardise results, complete macroscopic agglutination, after 24 hours at 55°C., in one or more of the dilutions usually put up 1:100, 1:200, and 1:400, as against the normal serum control, has been recognised as constituting a positive result; this standard having been adopted by me in previous work.

It will thus be seen from the summary of results given in Table IV. that "sample swabbing" in the Alexandria District (Egypt) has only yielded 3 "carriers" among 310 non-contacts swabbed—i.e., a "carrier rate" of only 1 per cent. The standard of the Central Cerebro-Spinal Fever Laboratory, London, being adopted, this "carrier rate" would be lower still.

#### General Conclusions.

The foregoing studies of cerebro-spinal meningitis in Egypt add little that is new to our knowledge of the disease and its prevention. But, they afford a striking confirmation of the hypothesis previously advanced by us associating outbreaks with a high degree of atmospheric humidity when the meningococcus is about.

A "carrier rate" of only 1 per cent. among "non-contacts" taken at random in the Alexandria District (Egypt), and constituting therefore a fairly good "sample"—as against a rate 10 or even 20 times as high in England under similar circumstances, i.e., working with the same medium and technique—suggests an explanation of the comparative immunity of Egypt from the disease. With the meningococcus so little about, atmospheric humidity in Egypt gets little chance to precipitate outbreaks.

We have indicated by ventilation studies, based on the hygrometric state of the atmosphere met with indoors in occupied quarters during sleeping hours, how the greatest attention requires to be paid to ventilation as a corrective to overcrowding, in view of keeping the indoor humidity as low as possible,—considering the part attributed by us to atmospheric humidity in the aetiology of cerebro-spinal fever.

#### APPENDIX.

## MALARIA FROM THE SURGEON'S STANDPOINT.<sup>1</sup>

By MARGUERITE WHITE, M.D.,

ATTACHED ROYAL ARMY MEDICAL CORPS; SURGICAL SPECIALIST, ST. ELMO MILITARY HOSPITAL, MALTA.

THE only type of malaria to be considered from the surgeon's standpoint is the subtertian or malignant tertian. In the quartan type the *Plasmodium malariae* goes through the entire process of reproduction in the circulating blood, and does not especially accumulate in any one organ or produce special effects. The tertian type, produced by the *Plasmodium vivax*, also goes through its life-cycle in the blood, and although the tertian sporulating forms are found in the internal organs, such as the spleen, they do not tend to accumulate in these organs or produce special effects. The third type, the subtertian or malignant tertian, caused by the æstivo-autumnal parasite, sporulates almost entirely in the internal organs, attacking any organ and producing symptoms peculiar to the disease of that organ: on the heart causing endocarditis or myocarditis, on the lung a pneumonia, on the spleen a splenitis and perisplenitis, on the pancreas an acute hæmorrhagic pancreatitis, on the liver a hepatitis, &c. Castellani and Chalmers, in writing of subtertian malaria, say:—

"These parasites seem to affect the red corpuscles so profoundly that they are liable to adhere to the walls of the capillaries, in which the parasite sporulates: hence it may produce severe local symptoms, due to the mechanical blocking of capillaries and the intense local action of the toxin; thus it is associated with what is called the malignant fevers—i.e., the fevers which produce local effects on one or more organs."<sup>2</sup>

In two and a half years on the island with the British Expeditionary Forces the number of cases I have seen in which malaria has proved to be the direct cause of surgical ailments referable to one organ have been comparatively small and with a very small mortality. Malaria as a complication in surgical cases and malaria simulating certain diseases are far more common, especially the first, where all the symptoms may indicate some other illness, for instance, after a gunshot wound of the head (and this is frequent) the symptoms may all point to a cerebral abscess, but under quinine therapy the urgent symptoms disappear and recovery is uninterrupted.

The classification is only made for the purpose of descriptive surgical pathology. Clinically, it is all malaria, and the treatment spells quinine and quinine only. In some of the sequelæ of malaria surgery may have to be resorted to, as in cases of ruptured spleen or the splenomegaly of chronic malaria, drainage of the abdomen in malarial cirrhosis, &c. Decapsulation of the kidney has also been done for suppression of urine in cases of blackwater fever on the island.

#### Reports and Discussion of Cases.

A number of cases were recorded, but, space does not permit of all being printed.

CASE 2. *Acute hæmorrhagic pancreatitis due to malaria.*—Patient, aged 26, invalided for malaria and admitted with this complaint. He was in hospital about six weeks; he had three slight attacks of malaria (subtertian), rings and crescents found in blood. The clinical findings were nil, except a palpable spleen, temperature in each attack not

<sup>1</sup> Paper read before the Conference of Medical Officers, Malta.

<sup>2</sup> Text-book on Tropical Medicine, by Castellani and Chalmers.

higher than 102 F.; patient recovered rapidly from attacks. General health excellent; sent to convalescent camp and a few weeks later to active service camp. After about a week at the latter he was readmitted as a surgical case. While on duty, he was suddenly seized with a severe pain in upper abdomen; carried to his tent. He was sent to hospital immediately.

On admission he was very collapsed, sweating profusely; pulse 120, weak and intermittent; abdomen distended and rigid, with marked resistance in epigastrium; drawn anxious look; temperature 98°; a few hours later 101°; appeared very ill. At laparotomy a few hours later there was some free bloody fluid in the abdomen; pancreas was enlarged and congested; small petechial hæmorrhages and fat-necrosis in surrounding tissues and mesentery. Appendix normal; liver and spleen slightly enlarged and congested. The abdomen was closed without drainage; intramuscular quinine gr. 10. During the first 24 hours after operation he collapsed twice; stimulants, artificial respiration, and oxygen. Next day he was much better, but sweating profusely. After this, under quinine, recovery was rapid and uninterrupted. He was allowed up at end of second week. Temperature became normal on the third day and remained so as long as patient was in hospital.

I have seen one other case on the island in which the diagnosis was made of acute pancreatitis, which cleared up rapidly under quinine. Surgical interference is contra-indicated, as the pancreatitis is due to a capillary thrombosis formed by the massing of the parasites and pigment.

These malarial abdominal infections are always due to the subtertian parasites, and if the parasites attack one particular organ there will be symptoms referable to that disease. In this case the pancreas was the principal organ to be attacked, and the symptoms were those of an acute pancreatitis from other causes. This explains the rapid recovery of these patients under quinine therapy if promptly and efficiently given, otherwise they rapidly die, or the organ becomes so damaged that it is unable to perform its function.

*Pseudo-appendicitis.*—I have seen many of these cases on the island due to malaria, which cleared up rapidly under intramuscular quinine. If the diagnosis is made surgical interference is not necessary. The cause of the pain on the right side is, I believe, a referred pain due to an acute splenitis, which, in my own observations, has always been present, although in some cases it may be due to the localisation of the parasite in the intestinal mucosa.

I have had many cases of appendicitis, both catarrhal and suppurative, in malarial patients and the only point in the differential diagnosis, as far as I have been able to observe, is the white cell count. In both classes of cases all Murphy's symptom-complex are present except leucocytosis—i.e., pain, vomiting, a little temperature, and rigidity of the right rectus. In pseudo-appendicitis or pseudo-cholecystitis due to malaria one finds a marked leucopenia, with a decrease in the polymorphs and a high mononuclear count. In true cases of appendicitis complicated with malaria one finds a relative leucocytosis, with an increase in the polymorphs. The non-discovery of the malarial parasites in the peripheral blood is of no account in the diagnosis.

*Malarial attack following operation.*—The following explains why an operation brings on an attack, and often of a very severe nature, and nearly always atypical in persons who have never previously suffered from one.

"It is a well-known fact that the plasmodium can exist in the spleen of persons who show no signs of fever or malaria cachexia, and go through their life-cycle there, but it would appear that they are restrained from invading the circulation by the action of some antitoxin and, therefore, do not increase to such numbers as to cause toxic symptoms. Thus it is obvious if the restraining influences which conduce to the condition of latent malaria are removed, an attack of malaria will follow."<sup>3</sup>

It is practically always the condition of latent malaria in patients which is the most annoying, though rarely fatal, complication in surgical cases. These patients give no history of having had malaria, and usually a history of perfect health up to the time they were wounded. The surgeon operates quite confidently that everything will be all right, then 24 to 48 hours after operation an impending attack of malaria is often foreshadowed by these symptoms, and I have noticed this especially in bone and joint cases. The patient complains of severe pain in the wound; the

latter looks unhealthy; joints often become very swollen and exquisitely painful, the least movement causing much pain. The temperature at this time is subnormal, but in a few hours rises to 105° or 106°, without a rigor. If I happen to see the patient at this stage, I give immediately quinine gr. 15, intramuscularly.

I have had a number of these cases under my care, and have found that the impending attack cannot be prevented by giving quinine at this stage, although it may be considerably shortened, and by giving another dose, also intramuscularly, the next day a second attack is rare.

Delayed wound healing is also a feature in this type of case. Wounds look unhealthy, granulate over, only to break down again in a few days. Some of them resemble syphilitic sores, and often it is only with a negative Wassermann and response to quinine therapy one becomes convinced that malaria is the ætiological factor.

I have never seen these conditions in known treated cases of malaria. As a prophylaxis against post-operative attacks of malaria I have found 15 gr. of quinine intramuscularly the night before operation extremely valuable.

*CASE 7. Camouflaged malaria.*—Patient aged 21. Service 3½ years. Had been in Salonika one year. Admitted to St. Elmo Hospital on diagnosis of gunshot wound of right elbow-joint. No history of malaria or dysentery; had felt well up to time he was wounded. On admission temperature 102°, pulse 118. Patient very weak and anæmic; great pain in arm; headache, dizziness, and ringing in ears. Examination revealed very little apart from the wounded arm, which was swollen, cyanotic, and tender from shoulder to fingertips. Elbow especially swollen; pus streaming out of a pin-point opening on anterior side just over brachial artery. Glands in the axilla were enlarged and tender. Day after admission severe headache; face very flushed. He had several fainting attacks; proposed operation for drainage of elbow-joint postponed. Temperature 102°; pulse 130, very weak and intermittent. Strychnine and digitalis were given during the day.

Next day his general condition had improved somewhat, and under ether anaesthesia the elbow-joint was drained; no attempt at resection on account of serious condition. During the next two days he improved greatly. Temperature not above 99° and pulse 100; ate well and slept well; complained of nothing but a feeling of giddiness, which he said he had had for some weeks before he was wounded.

On the evening of the second day following his operation, without any warning, and while talking, he had three severe epileptiform convulsions, became very violent, and relapsed into unconsciousness. Next morning, as he was still unconscious, a lumbar puncture was done; spinal fluid under greatly increased pressure, but clear. A white blood count was made and film taken for malaria; catheterised specimen of urine showed a faint trace of albumen, but no casts. The bacteriological report of spinal fluid negative; sugar reaction present. Films negative to malaria. White blood count was 8600; polymorphs, 60 percent.; lymphocytes, 29 percent.; large mononuclears, 5 percent. Patellar reflexes were absent; Babinsky and Kernig signs absent; some slight retraction of head. Major W. H. Kiep examined the eyes; report negative.

During the next 24 hours patient still remained unconscious; temperature, 102°; pulse, 130; involuntary urination and defecation. Lumbar puncture; fluid still under greatly increased pressure, but clear; bacteriological report as before; films again negative to malaria. The arm looked unhealthy and the edges of the wound gangrenous, with a very offensive odour; amputation was discussed, but decided to try intravenous quinine first. Quinine hydrochlor., gr. 15, in 10 oz. normal saline given; another lumbar puncture at same time. Two hours after the injection he commenced to perspire profusely; 16 hours later perfectly conscious; temperature, 98°; pulse, 90; patient very weak.

From this time recovery was uninterrupted, quinine hydrochlor., gr. 15, was given daily intramuscularly for a week, then twice a week for four weeks. The arm cleared up rapidly. During the next ten weeks in hospital he had no further rise of temperature and was sent to England as a walking case. Malaria parasites were never found in the blood, and the spleen was only just palpable.

This was a case of camouflaged malaria, where all symptoms indicated some other illness. The septic condition of the arm followed by the sudden coma pointed to an extension of the infected foci to the brain, with a resulting cerebral abscess, especially with the negative history of malaria and the absence of parasites in the blood. The white cell count and the absence of any localisation symptoms were the only two factors in the probable diagnosis of a cerebral malaria. Later the prompt response to quinine therapy and the rapid recovery left no doubt as to the diagnosis.

<sup>3</sup> From Text-book of Castellani and Chalmers.

The complications of camouflaged malaria are the most fatal in surgical cases, as they are usually rapidly fatal, and while one is trying to make a diagnosis the patient dies. Castellani, in writing of cerebral malaria, says:—

"No diagnosis of hemiplegia or of any brain or spinal disease without such obvious cause as traumatism should be made in malarious districts without first examining the blood to see whether the subtertian parasite is present."

I do not think he goes far enough in this statement, as in the most serious and fatal of my cases parasites have never been found in the peripheral blood. Splenic punctures have not been made, or the parasite would undoubtedly have been found there, but I have relied on the white cell count, especially in the presence of suppuration and the large spleen, and corroborated it by the final test of the response to quinine therapy.

A case (No. 8) was recorded of *purpura hæmorrhagica* due to malaria, or, as Castellani calls it, hæmorrhagic pernicious fever. Fortunately this very fatal complication is rare. The hæmorrhages appear during the attacks but never during the intermission. Untreated it rapidly produces severe anæmia, with thread pulse, delirium, and death; often all treatment is of no avail. Operations on these patients are absolutely contraindicated unless it is the question of the life of the patient, and then every precaution should be taken to guard against and prevent hæmorrhage. Even the extraction of a tooth has led to fatal results in these cases.

The relation of quinine to hæmorrhages is still a debated question. My own experience tends towards the view that the quinine has very little, if anything, to do with it. Where I have observed a tendency to hæmorrhage in malarial patients post-operative or otherwise I always give quinine hydrochlor. in small doses, with large doses of calcium lactate and, if necessary, horse serum.

The last case recorded (No. 9) was one of amputation of the leg. The most interesting thing about this case is that for nearly two years under certainly not the most ideal conditions in Salonika the patient had no relapse of malaria in a known subtertian infection. I mention the case especially as it proves that the parasite may remain dormant for years in the system and the patient in perfect health. Suddenly it may light up when the vitality of the body is lowered and produce an attack of a very serious nature. Also the sudden acute dilatation of the heart in these cases is very common, often proving fatal.

#### Conclusions.

These surgical manifestations, complications, and sequelæ usually result from a neglected and undiagnosed malaria or from a malaria inefficiently treated with quinine. The fact that there have been so few on the island speaks well for the promptness and efficiency of the treatment and the correctness of diagnosis.

There is no difficulty in recognising the quartan and the simple tertian variety, as the attacks are usually typical and parasites can always be found in the peripheral blood if films are taken at the proper time. The difficulty in diagnosis is the subtertian, with its many masks and innumerable sequelæ, and it is this type which is most often untreated because undiagnosed.

It is to be doubted whether any of us realise sufficiently what a protean disease malaria is, and the points to be emphasised are:—

1. That an operation often brings on an attack of malaria of a very severe nature, and an acute dilatation of the heart during or following an operation is very frequent, often proving fatal, and the utmost precautions should be used in regard to anæsthetics for these malarial patients. Ether given by the Vernon Harcourt method is the safest; chloroform, in my opinion, is absolutely contraindicated.
2. That the malarial parasites of subtertian malaria may attack any organ, giving all clinical symptoms of disease of that organ, as the surgeon who has no experience of malaria will find to his cost.
3. That the negative history of malaria and the absence of parasites in the blood is of no account in the diagnosis of a positive malaria.
4. That in a malarial patient convulsions and coma occur in an apparently healthy man without any warning, and that it is not uncommon for a man with acute cerebral malaria to be arrested for drunkenness; and that in every case of brain or spinal disease, or other obscure complaints occurring in men who have been East, malaria is one of the first things that should be considered by the surgeon.

5. That the subtertian malaria may simulate almost any disease, surgical, mental, or medical. It may produce such insidious symptoms that when the patient feels ill enough to see a doctor treatment is of little avail.

6. In the acute attacks there may or there may not be a chill, and parasites may or may not be found in the blood in this type.

The patient may have no idea himself that he has malaria, and herein lies the danger. A man with a subtertian infection is always in danger of his life, and too much importance cannot be attached to the question as to the care of these malarial victims in England after they return to their homes. As Professor Osler wrote some years ago: "There is no other disease which compares with it, except perhaps tuberculosis, in the extent of its distribution and its importance as a killing and disabling disease."

## Clinical Notes.

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### A CASE OF MULTIPLE EPULIDES.

BY W. WARWICK JAMES, F.R.C.S. ENG., L.D.S.,  
DENTAL SURGEON, ROYAL DENTAL HOSPITAL; ASSISTANT DENTAL  
SURGEON, MIDDLESEX HOSPITAL, ETC.

IN the following case the growth of a fibrous epulis (to be more definite, hypertrophy of the fibrous tissue of the gingival muco-periosteum) has been associated with each tooth of the temporary and permanent series which has erupted.

#### Account of Case.

The patient, a girl now aged 11, was admitted into hospital in May, 1912, when a portion of the tissue was examined microscopically. Some uncertainty existed as to its nature. A further section showed it to be purely fibromatous.<sup>1</sup> The gingival margins were considerably enlarged and nodular. The tissue particularly involved was apparently the gum margin and the neighbouring portion, but not the greater part of that covering the roots. As the result of treatment it would seem that the periodontal membrane is also involved, the bone is not involved; X ray photographs showed no changes. The growth had extended round the crowns, in parts even reaching to the top of the teeth, and also in thickness. In the early stages it appears markedly vascular and somewhat denuded, but later it seems less vascular and is mottled with faintly yellowish-brown patches. There was no tendency in the tissue to break down except where injured by opposing teeth. Growth is slow, the increase being marked by months rather than weeks. Patient suffered no pain; general health seemed affected, probably owing to difficulty in eating. The growth superficially resembles a simple fibrous epulis, but is sessile, while the simple epulis is nearly always pedunculated.

Of particular interest is the effect of treatment, and this coincides with the records of other cases, and of that of a simple fibrous epulis. Seven separate operations have been performed and an attempt was made to save the teeth, but recurrence followed. All the temporary and eight of the permanent ones have been extracted, the growth completely excised, and the margins of the alveolus removed. The stages of the operations were as follows: All the temporary incisors and the first temporary molars were extracted and the growth removed, whilst the abnormal tissue was cut away freely down to the bone margin round the remaining eight teeth. Where the teeth remained the growth recurred and in July, 1912, the four molars were removed as being less accessible than the canines, and the tissue again pared away round the latter. In October, 1912, the canine teeth were similarly treated. The child was now nearly 5 years old.

No change took place for about two years, nor was there any sign of a similar growth until after the first permanent molars appeared, when the condition recurred in about a year and the previous operation was repeated. In October, 1917, the maxillary incisors had erupted, with recurrence of the condition, and although it was suggested upon the lower incisors it was not marked. An operation removing the tissue around the upper incisors without the teeth was unsuccessful and the teeth were removed in November.

The present condition shows the lower canines involved, also the left lower second premolar, which is erupting into the socket of the first permanent molar. The same change

is taking place with regard to the right upper premolar, which is erupting into the socket of the first permanent molar. The gum presents the reddish, somewhat denuded appearance described, which seems the first indication of the growth, although in parts it is reaching the nodular stage. The patient has been wearing a vulcanite block to bite upon; the pressure from this seems to have arrested the development of the condition in one part.

#### Remarks.

The child has been strong and healthy from birth, except for whooping-cough and an attack of what the mother describes as "dry eczema" prior to the appearance of the mouth condition at the age of 3 years. No rickets. She was not nursed for more than a few weeks.

She is not a mouth-breather, a fact of interest, as much hypertrophy of the gingival tissues is frequently seen in the front part of the mouth in such patients. Such a condition is of an infective nature, and the changes are in marked contrast to those in the present case. In mouth-breathers the swelling of the tissues conforms accurately to the line of contact with the lips, so that when the lips are pulled back there is no hesitation in saying that mouth-breathing exists. In cases of hypertrophy the lips may be apart on account of the bulk of the growth. The condition in this patient would probably be described as hypertrophy, and although a certain number of cases have been recorded, they are undoubtedly rare.

The hypertrophy seen in adults is generally due to chronic infection, and involves the bone as well as the gingival tissue. Perhaps the commonest type is a marked thickening of the bone and the gum in the region of the maxillary molars, although several cases have been recorded where the whole of the alveolar margin has been involved, but the maxilla appears to be affected more often than the mandible in children.

Christopher Heath has described a similar case to the one now reported. Cases mentioned by him occurred at the ages of 8, 2½, 7, 4, and 2 years, the three latter in one family. In all the cases recorded the mental condition was defective. In another case recorded, very similar to the present one, the child was 4½ years old and healthy. After describing this case, he says, "In conclusion I should say that nothing less than complete removal of the affected alveolus seems to offer any hope of alleviating these cases." As far as I can ascertain, the length of history of this particular case is greater than that of any recorded cases.

As it is difficult definitely to classify these cases, the term *epulides* is used in its widest sense, but if they were allotted to a definite class, it is probable that hypertrophy would be the correct description. It seems a very drastic procedure to remove every tooth and so render the child edentulous. It is true we can provide an artificial substitute, if nothing short of extraction can be accomplished.

#### A CASE OF HERMAPHRODISM.

BY W. DANNE, L.R.C.P. EDIN., L.R.C.S. IREL.

THE following case is described on account of its rarity. The only similar one I can find is in the 1891 edition of "Diseases of Women" by Gaillard Thomas, but in his case there were both scrotum and testicles. It would be interesting to learn if anyone else in this country has seen a similar instance.

Quite lately a woman with well-developed breasts and nothing characteristic of a male in her voice or general appearance was brought to me. She was 40 years of age and was going to be married soon, but as she had a "lump in the privates" she wished me to remove it. On examination there was no trace of a vagina and the "lump" proved to be a small, well-formed penis, with prepuce, which could be retracted and the glans exposed. This penis was capable of erection, and per urethram she menstruated regularly every month as well as micturated. Also she appeared to have nocturnal emissions at intervals, with sexual feeling. Per rectum the anterior rectal wall was very thin, and through it, lying towards the left, could be felt a modified uterus of a fair size, but with only one cornu. I could find neither ovaries nor testicles, and no evidence of a scrotum.

I told her nothing could be done to fit her for marriage, and this opinion was confirmed by Mr. D. C. Rayner. As she still was anxious that something should be done I sent her to Dr. James Oliver, who agreed that it was a case for which no operation was possible.

Bristol.

## Reviews and Notices of Books.

*The Early Diagnosis of Tubercle.* (Oxford Medical Publications.) By CLIVE RIVIERE, M.D., F.R.C.P. Second edition. London: Henry Frowde; Hodder and Stoughton. 1919. Pp. 314. 10s. 6d.

THE second edition of Dr. Riviere's book on the early diagnosis of tuberculosis is quite a bulky volume for a work limited to a single aspect of one disease. The author in his preface notes that the present edition has been revised and expanded, and that, for the first time, a fairly adequate description is given of hilus tuberculosis in the adult. This book is excellent, but it is impossible to read it without coming to the conclusion that the author has evolved a machinery so complicated that many of his readers will feel baffled as well as helped by it. As he says: "..... Many of the older methods have been amplified and improved, and valuable new ones have been introduced." Would that he had been more willing to "scrap" as well as to amplify and improve! The author is an enthusiastic "percussionist," and he attaches far more importance to percussion than to auscultation of the chest. There can be no doubt that he has reduced, or let us rather say exalted, percussion to a fine art. Take the following sentence for example:—

"Gentle percussion is of two kinds: (a) One in which the soft stroke is 'carried through,' whereby the depths of the lung are reached more truly than by heavy percussion; (b) what may be called light, 'flipping' percussion directed to the discovery of surface changes, and whereby a thickened pleura may, perhaps, be distinguished from impairment due to underlying lung."

It is clear that the author has not only assimilated all the available teachings of the art of percussion; he has added to it himself. But there is surely as little hope of his readers gaining the same skill in percussion as of Paderewski turning out pianistic replicas of himself by writing a text-book on his art. The author's praise of the X rays is measured, and he has found that in most cases they are superfluous. Having damned them with a halting testimonial, he proceeds to give an excellent account of their interpretation in disease of the lungs—an account which is the more concise, objective, and detached for being given by an agnostic. The chapter dealing with tuberculin reveals the author's wide knowledge of a subject obscured by the prodigious output of mediocre workers; and he has reduced his encyclopædic raw material to an eminently readable and concise finished product. But in the chapter on the temperature he has edited his sources of information with less discrimination, and instead of confining himself to the best monographs on the subject, he quotes over a score of writers, leaving the reader to pick out what he likes best. Part II. deals with tuberculosis in children and represents about one-third of the book. Here the author contributes much useful information, full measure, pressed down.

This book is first-class matter from a first-class source; its chief fault in this age of haste is a surfeit of information, and it is to be hoped that the third edition, which will no doubt soon be called for, may show more signs of condensation than of expansion.

*Dental Surgery and Pathology.* By J. F. COLYER, F.R.C.S., L.D.S., Dental Surgeon to Charing Cross Hospital and the Royal Dental Hospital; Examiner in Dental Surgery, Royal College of Surgeons of England. Fourth edition. With illustrations. London: Longmans, Green, and Co. 1919. Pp. 899. 32s. net.

THE importance of a knowledge of pathology to the dental surgeon can hardly be over-estimated; for now it is becoming universally recognised that the gravest results may follow septic processes in the mouth, and that many general diseases are to be attributed directly to infection proceeding from this source. It is clear, therefore, that we must look to the dental surgeon for the recognition of the existence at an early stage of those septic conditions which may, if neglected, prove to be the forerunners of very serious morbid conditions. Dental students, therefore, are fortunate to be in a position to possess such a work as this in which the true principles of pathology in relation to the teeth are fully expounded and clearly enunciated. The ideal principle of dental treatment

should ever be the prevention of sepsis, and the ideal of dentistry will only be attained when preventable diseases associated with the teeth shall have ceased to exist.

Mr. Colyer has described fully all the abnormalities to which teeth are subject, and the methods by which these abnormalities may be remedied; he has discussed very thoroughly all the theories as to the nature and causes of caries, and he comes to the conclusion that the prevalence of caries in modern races is due to the soft character of the food and the increase in the use of carbohydrates which undergo rapid fermentation. The importance of periodontitis is fully recognised, and the author finds that the evidence points to the disease being started by injury of the gingival margin from food débris or by the local action of toxins as seen in the marginal gingivitis of mouth-breathers; and the prevalence of the disease at the present day he attributes to the character of modern diet, for much of our food is prepared in such a way that it accumulates readily round the teeth and is of a nature easily to undergo fermentation. The chapter on fractures of the jaw is adequate, and no excess of space is devoted to gunshot fractures, for in civil practice such fractures are very rare.

There are two points in this work that deserve special mention. One of these is the very full provision of illustrations—a sufficient number of illustrations goes far to assist the student in the thorough comprehension of a subject. The other point is the very complete index. A work like this should prove of interest not only to dental students and dental surgeons, but also to very many members of the medical profession who have nothing directly to do with dentistry; from it they will learn much that will be of value in the treatment of patients suffering from many diseases, and they will appreciate more fully than many do now the importance of early attention to morbid conditions of the teeth in the treatment of disease in other parts of the body.

#### JOURNALS.

*The British Journal of Children's Diseases.* Vol. XVI., April-June. Edited by J. D. ROLLESTON, M.D.—Dr. Edmund Cautley contributes an article on Duodenal Stenosis, in which he reviews the literature and reports a personal case in a male infant aged 12 months. He states that the characteristic feature of the condition is vomiting, with the usual signs of obstruction. It may occur even if no food is given by mouth, the stomach becoming distended by normal secretion. Bilious vomiting occurs in about 90 per cent. of the cases, and if the obstruction is above the entrance of the common duct is probably due to an aberrant branch opening into the dilated first part of the duodenum. Hæmatemesis is not uncommon. Inanition, wasting, and constipation naturally develop. If food is taken and life prolonged, as in some cases in which adult life and even middle age have been reached, the stomach and first part of the duodenum become dilated and hypertrophied, and there is marked gastric peristalsis. The symptoms are practically the same as those of congenital hypertrophic stenosis of the pylorus, unless bilious vomiting is also present. A dilated first part of the duodenum gives the sensation of a pyloric tumour, but it is neither so hard nor so defined as in pyloric hypertrophy. No medical treatment is of real benefit, but life has been saved in isolated cases by early operation. Many of the infants are premature. In Dr. Cautley's case an exploratory operation was made, but the state of the child did not warrant gastro-enterostomy and death took place a week later. At the autopsy the stomach was found to be dilated and hypertrophied, and the pylorus widely dilated. The first part of the duodenum was dilated into a more or less spherical sac over 2 in. in diameter. The second part for a distance of an inch was extremely stenosed, merely admitting the passage of a probe, and the duct entered about the middle of the stenosed portion. There were no other abnormalities.—In a paper on Catarrhal Jaundice in Children, Dr. E. Bronson reports a number of cases of catarrhal jaundice associated with influenza in children, and classifies them under the following groups: (1) those in which jaundice followed exposure to influenza, but which did not develop influenza in the ordinary sense; (2) cases which developed jaundice as a sequel to an attack of influenza; (3) doubtful cases in which there was no known exposure to influenza.—In a Note on Influenza in Infants, Dr. C. Achard, of Paris, states that though one of the peculiarities of the present epidemic has been the rarity of the disease at this age, he has had the opportunity of observing 32 cases under 2 years of age in the crèche at the Hôpital Necker. In six cases the disease was uncomplicated and recovery took place, in 12 there was bronchitis or slight pulmonary congestion with one

death, and in 13 broncho-pneumonia developed with seven deaths. Achard concludes that influenza in the infant is by no means exceptional, and that the form and gravity of the disease may vary. The infant does not possess any real immunity but is merely less exposed to contagion from without, the infection being chiefly contracted from the mother.—Mr. Ralph Thompson records a case of Ectopia Vesicæ, in which he performed a successful operation in the fifth month of life. In his discussion of the anatomy of the condition he comes to the following conclusion: (1) Ectopia vesicæ is a body cleft due to the formation of a groove in the allantois, which secondarily affects the cloaca; (2) epispadias is not analogous to hypospadias, but is evidence of a bifid or double genital eminence being formed from the cloaca which is cleft secondary to the allantois; (3) the cause of the deformity must be above rather than below.—A case of Urethrocele is described by Mr. Pybus in a male child, aged 3 years. The penis was considerably enlarged, measuring  $3\frac{1}{2}$  inches in length, and became ballooned during micturition. The urine was ammoniacal and contained pus. Death took place a week after an operation at which the redundant portion of the urethra was removed. The autopsy showed considerable hypertrophy of the bladder, marked dilatation of the ureters, and of a less degree of the renal pelvis, one of which was inflamed.—Dr. Parkes Weber and Mr. T. H. Gunewardine report a new case of Lipodystrophia Progressiva in a girl aged 12½, in whom the disease had set in five years previously.—Dr. John Thomson contributes a note on a case of Myasthenia Gravis in a girl aged 11½ years, which proved fatal in nine months' time.—Mr. Haldin Davis gives an account of the Willesden Ringworm Clinic, which he established in the spring of 1913, since when 441 cases had been submitted to X ray treatment. No instances of X ray burn or permanent alopecia occurred. Owing to the speed with which cases can be cured by X rays, Mr. Davis states that the cost of treatment is nearly defrayed by the additional grant earned from the Board of Education and by the saving of school time which would have been lost under the older, slower methods of treatment.—A Retrospect of Otolology, 1918, is contributed by Mr. Macleod Yearsley.—The abstracts from current literature are devoted to acute infectious diseases, disorders of metabolism, diseases of the urogenital system, dermatology and syphilis, and otology, rhinology, and laryngology.

In the *Military Surgeon* (Washington, D.C., U.S.A.) for April Colonel Qualls and Captain Meylackson give an account of a large venereal clinic in Maryland. The clinic received about 50 fresh cases daily; some 85 per cent. of the infections were contracted in civil life, 9 per cent. of whites and 39 per cent. of negroes being found infected on entry. Details of the organisation required to deal rapidly and effectively with this mass of cases are given, and should be read by all interested. In 13,159 persons treated by prophylaxis 126 cases developed, but only 11 amongst those who took the treatment within an hour of exposure.—Captain L. C. Frost insists that cases of shell shock must be treated at once by experts within the battle area.—Colonel Lynch and Lieutenant-Colonel J. G. Cumming urge that infection of sputum-borne diseases in the army occurs rather through mess utensils than by the air of the barrack-room, and set out the need for washing these in water that is boiling. They found that in certain civilian groups, numbering in all 20,000 people, those whose dishes, &c., were machine-washed suffered far less from influenza than did those whose mess-kits were washed by hand. They desire to see a lavatory established near the mess-room in all barracks, so that the men may get into the disease-averting custom of washing the hands before each meal. They found that even in a smart regiment not quite a quarter of the men do so now. The U.S. base hospital at Etretat learned to save their orderlies from trench fever by cleaning patients on entry, and by putting the orderlies dealing with new entries, their clothing and effects into louse-proof suits, double pyjama suits sprayed with creosote oil. One clerk appeared to have become infected through carelessly sitting on the stretchers of the new entries while taking their "particulars."—Major Dodge, reporting on 638 operations for hernia, mentions that after it became a routine for all operation cases to gargle with a 1 in 10,000 solution of quinine sulphate post-operative pneumonia ceased to occur, and no one using that gargle got pneumonia during the October influenza epidemic, though several had influenza. The quinine gargle is supposed to be specific against the pneumococcus.—Lieutenant-Colonel J. T. Rugh discusses leggings and puttees, and concludes that no complaint can be made against them if they fit.

**CENTENARIANS.**—Mrs. Esther Carter died recently at East Molesey, Surrey, in her 102nd year. The deceased was born at Weymouth, and visited her birthplace upon the 100th anniversary of her birthday.—Miss Eleanor Patteson, who completed her 100th year two months ago, died on July 18th at Bath.

# THE LANCET.

LONDON: SATURDAY, JULY 26, 1919.

## An American Hospital in London.

WE publish in another column the account of a notable meeting held at the House of the Royal Society of Medicine on Thursday, July 17th, when the formal foundation was inaugurated of an American Hospital in London, to be a rallying point for American post-graduate students and all members of the medical profession in America sojourning on our side of the Atlantic; to be the natural shelter for American citizens in our midst and needing hospital attention; and (to quote the words of the main resolution epitomising the movement) "to commemorate the coöperation of the medical men of the United States and of Great Britain during the European War and to strengthen the friendship existing between the two nations." Lord READING, who presided at a meeting which was characterised alike by the brevity of the oratory and the directness of the results, said happily and wittily that the case for the foundation of an American hospital in London was so strong that had he been sitting "in another place" he must immediately have given judgment in favour of its supporters. And this must be the verdict of all who have thought over the matter.

The foundation of the American Hospital in London has been largely the conception of Mr. PHILIP FRANKLIN, an American citizen some years resident in England, a Fellow of the Royal College of Surgeons of England, and a member of the honorary staff of many institutions, civil and military. To his energy, prevision, and tact the fact is owing that the hospital has now been definitely founded, and founded with the remarkable promise of success which is sufficiently indicated by the names pledged to support it. And if ever the right seed was sown in the right soil at the right time this was such a fortunate sowing. Mr. FRANKLIN has practically found no critics of his idea or intention, though we may be perfectly certain that he came across many whose approval was more verbal than practical. We have in these columns on many occasions alluded to the fact, not so difficult of explanation as it may appear, that the vast city of London has not hitherto been recognised as a centre for post-graduate medical teaching by foreigners, while until recently what post-graduate teaching there has been has been individual, sporadic, and ill-organised. Greater London, with a population of about seven millions and an area of seven hundred square miles, containing within its boundaries all sorts and conditions of men contracting, or liable to contract, every pathological condition that can occur in an inclusive index of disease, has never been sought out by foreigners, and not even by our blood relatives who speak our tongue, the Americans, as a post-graduate centre. The fault has been our own, and is only partly condoned by the fact that the enormous figures concerned have rendered any complete system of inter-organisation difficult. Our wealth of material has never until now properly been centralised; our far-scattered hospitals have only recently begun to join in a unified plan of

education; while for the stranger, and even for the American guest, there has been as yet no centre at which he could obtain information or get into some human relations with his professional colleagues in this country.

The American Hospital is to prove itself a visible sign of a complete change of spirit. As is well known, there is in London now a post-graduate scheme in connexion with the Fellowship of Medicine, and this organisation, started on emergency lines, is sure to develop into a permanent organisation. The American Hospital, over and above its position as a general hospital ministering to American needs, will be the place where the American doctor will turn instinctively when he arrives on our side of the Atlantic for multifarious information as to how, having such and such time at his disposal, and such and such money to spend, and such and such plans for the completion and development of his medical education, he should best proceed. The information given him will enable him to make full use of such post-graduate organisation as we have, while his presence among us will spur us on to see that that organisation is good and intending to be better. Then will London take its rightful place as a great post-graduate centre.

## The Study of Wound Shock.

THE fundamental cause of wound shock still remains obscure. With this confession of ignorance Captain N. M. KEITH, R.A.M.C., opens a report<sup>1</sup> of the special investigation committee set apart by the Medical Research Committee to inquire into surgical shock and its allied conditions. And he goes on to say that, while no single ætiological factor can be recognised as the invariable initial cause, the various secondary factors which obviously contribute in many instances towards the production of the finished article are in no better case, as when these are eliminated by early preventive treatment the condition of shock often persists nevertheless, and the patient succumbs. KEITH'S contribution is to make quite clear that reduction of total blood and plasma volume are striking and important features in wound shock; that after moderate hæmorrhage without shock the total blood volume is rapidly restored, while in shock itself recovery is accompanied by restoration of blood volume. An important indication in the treatment of serious cases of wound shock, therefore, is to increase the amount of fluid in the circulation, which can only be done by intravenous infusion. His observations help to diminish the complexity of the pathological picture of shock and to replace the vague assumption of nervous influence by substantial knowledge of altered blood states and changed blood volumes.

When KEITH began his work at a casualty clearing station in the spring of 1918 our conception of the pathology of wound shock was, speaking broadly, that of a condition of circulatory failure with low blood pressure and increased permeability of the capillaries, due to a combination of one or more of the factors of cold, pain, hæmorrhage, and toxæmia at work in an exhausted system. KEITH made available a new series of data—namely, the actual records of blood and plasma volumes. The old idea of the pooling of blood in the splanchnic area had already been abandoned by the Béthune

<sup>1</sup> N. M. Keith: Blood-Volume Changes in Wound Shock and Primary Hæmorrhage. Special Report Series No. 27. Medical Research Committee. H.M. Stationery Office. Price 9d.

group of investigators, but beyond observations on concentration of the blood no new facts then emerged. KEITH used the vital red method of measuring the blood volume direct, introduced by him in 1915<sup>2</sup> and used by ROBERTSON and BOCK in a parallel investigation.<sup>3</sup> Since vital red does not yet appear in the physiology text-books it may be well to interpose that it is a dye of the triphenyl-methane series, non-toxic and readily sterilised. Ten c.cm. or so of a 1.5 per cent. solution injected into a vein mixes uniformly with the circulating blood within five minutes, staining the plasma, so that a determination of the tint of a withdrawn sample enables the total blood volume to be calculated. On these simple colorimetric lines the diminished blood volume in soldiers suffering from wound shock was found to bear definite relationship to the severity of the patient's clinical condition. In the 29 cases studied the estimated blood volume ranged from 52 to 85 per cent. of the normal, while the plasma was correspondingly reduced to 62-90 per cent. In order to determine the part played by hæmorrhage in the deficiency of blood in the circulation observations were made on donors after supplying blood for transfusion. Withdrawal of quantities up to 800 c.cm. was followed by a rapid return of the blood volume to its original level. This level was sometimes reached within an hour, and occasionally the compensatory process persisted until an actual increase in blood volume resulted. When, however, the loss of blood is excessive, or when severe trauma is present, a shock-like condition follows which is distinguished by a failure of the normal process of rapid restoration. Shock may be accompanied by a fall in the circulating blood volume even without hæmorrhage. From a clinical study, combined with blood-volume observations, cases were divided into three groups:—

*Group I.*—The less severe cases, without distressing symptoms, with a pulse-rate of 90-110, a systolic blood pressure above 95 mm. Hg, and the blood volume not reduced below 75 per cent. of the normal.

*Group II.*—Into this class fall the serious cases, where the pulse-rate is 120-140, the systolic pressure below 90 mm. Hg, and the total blood volume between 65 and 75 per cent. of the normal.

*Group III.*—The men dangerously ill, with imperceptible pulse, a systolic pressure below 60 mm. Hg, a heart-rate of 120-160, and a blood volume below 65 per cent. (frequently 50-60 per cent.) of the normal.

In this third group, when the low pressure has continued for more than a brief period, recovery is almost impossible. The intracellular oxygenation of the tissues, including the sensitive cortical nerve cells, has been interfered with, and the damage cannot then be repaired even by transfusing whole blood. But KEITH reports the case of a soldier who had sustained an extensive comminuted fracture of the femur without external wound, in whom blood volume was reduced to 64 per cent. of the normal, pulse-rate 120, and maximum blood pressure 70 mm. Hg, but in whom, under warmth and fluids by the mouth, the pulse slowed, blood pressure rose, and the blood volume increased 400 c.cm. by the next day.

These observations should be read in conjunction with Mr. E. M. COWELL's instructive Arris and Gale lecture on the Initiation of Wound Shock, which we print in our current issue. Mr. COWELL's work is based upon blood pressure observations made over

a period of three years at various points in the firing line, and often actually in the front trench. Some of these observations have been recorded in an early report<sup>4</sup> of the special investigation committee already mentioned. Criticism has been levelled against the preponderance in this report of clinical data over practical deductions for treatment. But Mr. COWELL very rightly points out that once the knowledge of wound shock is brought on to a sound clinical and pathological basis the application of therapeutic principles will follow as a matter of course. His summary of recent investigations focusses very convincingly the varied sources of new knowledge on to a screen where their practical bearing can be clearly seen. It is now established that in cases of severe wound shock the infusion of normal or even hypertonic saline has but a momentary effect<sup>5</sup> on the circulation. In uncomplicated cases, too, sodium bicarbonate solution gives no better results. Transfusion of blood, or its substitute BAYLISS's gum saline solution, gives a more lasting rise in blood pressure, since the added fluid remains within the vessels. In KEITH's experience the results of gum and blood were practically identical, and the success or failure of either depended largely upon whether the blood volume was sufficiently restored after their injection. The subcutaneous route for fluid administration is useless, because of the sluggish peripheral circulation and consequent slow absorption. The futility of relying on any of the numerous drugs commonly recommended to raise the blood pressure is emphasised by Mr. COWELL and will readily be understood in the light of KEITH's work. These are important and fruitful deductions, and their application to the surgical shock of civilian practice should not tarry.

## The North-Eastern Railway Strike and Eyesight Tests.

LAST week the locomotive men and the firemen at Carlisle objected to the eyesight test laid down by the North-Eastern Railway Company, and came out on strike as a protest. The strike that ensued crippled all the industries on the North-East coast, the price of all food has risen, and the transport of passengers has been restricted to those who were able to hire motor-cars or aeroplanes. The National Union of Railwaymen negotiated with the North-Eastern Railway Company, and it is understood that they were united on one point—that the Board of Trade should speedily set up a national eyesight test. The strike has ended on this understanding. Hitherto, unfortunately, no standard of vision has been prescribed for the various railway employees; it rests with each company to make and enforce such regulations as they may consider necessary. As the safety of the travelling public is involved, this is clearly a matter for a Government department to arrange. The nature of the tests is for ophthalmic experts to decide, after being given every facility by the railway companies to learn the special visual requirements of the service. It is necessary to point out that the standard vision of 6/6 (or standard form sense) is by no means always associated with a good light sense, and for an engine-driver it is absolutely essential that he should be able to detect the signal lights readily

<sup>2</sup> N. M. Keith, L. G. Rowntree, and J. T. Geraghty, Arch. Int. Med., Chicago, October, 1915.

<sup>3</sup> O. H. Robertson and A. V. Bock: Memorandum on Blood Volume after Hemorrhage, No. 6, Reports of the Special Investigation Committee on Surgical Shock and Allied Conditions.

<sup>4</sup> E. M. Cowell: Investigation of the Nature and Treatment of Wound Shock and Allied Conditions, No. 2, same reports.

<sup>5</sup> J. Fraser and E. M. Cowell: No. 2 same reports.

on a dark night; indeed, this is much more necessary than a standard form sense. In a good light a candidate may pass all the usual tests with Snellen's types and the colour tests with Holmgren's wools easily, but he might fail deplorably if the light were dim. The lantern test with the necessary coloured glasses seems to be the best colour test for locomotive men and for sailors, but it would appear that more attention should be devoted to the examination of light sense.

The promise of the President of the Board of Trade, Sir AUCKLAND GEDDES, that a national eyesight test for railwaymen shall be established within a month comes none too soon. Indeed, it is regrettable that such a test was not established long ago, instead of leaving a difficult matter to be decided separately by each railway company, with the result of the dissatisfaction recently manifested on the North-Eastern Railway. In the case of the Mercantile Marine, in which similar dissatisfaction used to exist, a Departmental Committee was set up by the Board of Trade in 1912 and its recommendations for a national test were adopted, with results that are said to be satisfactory. On this committee two ophthalmologists held seats, and it is essential that in deciding on the railway tests also, ophthalmologists should be brought into consultation. One of the most important tests is that for colour vision. As has been proved by Dr. F. W. EDRIDGE-GREEN, the old Holmgren wool test is both inefficient and dangerous in that it rejects some who ought to be passed, while, on the other hand, a large number will pass it easily whose future employment is dangerous. The wool test has now been replaced by most, if not all, of the railway companies by some form of lantern test. This should be made compulsory, and no lantern should be used which has not means for regulating the luminosity of the lights shown, as otherwise a man who cannot distinguish in a fog between a red and a green light might be passed. The degree of visual acuity necessary for engine-drivers and firemen is a matter that certainly requires a uniform settlement. On one railway the present standard is 6/12 in the better eye, 6/18 in the worse, without glasses. Is 6/12 good enough? Is not 6/18 an unnecessarily high standard for the worse eye? A man with 6/6 vision in one eye and 6/60 only in the other would certainly have better vision with the two eyes than one with 6/12 and 6/18 respectively. The only disadvantage that the former might be under would be the possibility of getting a spark from the engine in his better eye. The question of the employment of spectacles should be answered, and a rough but efficient test for the visual fields should be established to exclude any with such disease as retinitis pigmentosa, in which central vision may remain good till a late period.

The detection of tobacco amblyopia is a matter of very great importance at the present time, when this disease is more prevalent than formerly. No man should enter the railway service without being told the facts as to tobacco blindness and the importance of taking early advice in case of gradual diminution of vision, which will often save him from the necessity of having to throw up his job. As toxic amblyopia is fairly frequent even in those who smoke with moderation, and as its characteristic symptom is the early onset of a macular scotoma for green and red, it would seem necessary for engine-drivers and watchmen to be tested for this complaint every six months or so; and locomotive firemen at least every

year. When recognised early, recovery may be almost guaranteed in eight or ten weeks, if the required treatment is duly carried out.

## The Emergence of the Health Visitor.

THREE classes of women have come to be very closely associated with the medical practitioner in his work as indispensable helpmates, whether on the remedial or preventive side. In order of emergence these are, of course, the midwife—whose history goes back into the unknown; the nurse—whose founder, in the modern sense of the title, was FLORENCE NIGHTINGALE; and the health visitor—who scarcely existed before the London County Council Act of 1908. The nurse's work is purely remedial, to her both patient and doctor alike turn in sickness; but medicine is becoming increasingly preventive, and unless specially trained in the mechanism of health the nurse may be as inadvertently dangerous to the well child as she is mercifully helpful to the sick one. The midwife's habitat is normal physiological function, and the Board which controls her strictly defines the variations from the normal which are her concern. The health visitor arose for the purpose of advising on the proper nurture, care, and management of young children, of promoting cleanliness as the basis of health, and of carrying out (in the words of the Act of 1908) such other analogous duties as might be assigned to her. No one then could foresee to what extent these analogous duties might grow in ten years' time or be expected to devise in advance the training best suited to meet them. The Local Government Board at that time regarded the full nursing certificate or the diploma of the Central Midwives Board as satisfactory evidence of qualification. Time has not justified this claim, and the most successful health visiting is now found to be done by women of good education with some previous training in social science. To define and promote the best type of training for the health visitor has for some time been an objective of the National Association for the Prevention of Infant Mortality, and the scheme for training just issued as Circular 4 (M. and C.W. 10) by the Ministry of Health may be regarded as the fruition of their labours. At the same time appear the draft regulations (Cmd. 255, price 1d.) of the Board of Education, laying down the conditions under which in future grants will be made in aid of health visiting. Briefly, a good preliminary education and a course of two years will be required of candidates without previous special training, one year to be devoted to theory and one to practice. In the case of fully trained nurses, previous health visitors, or those holding a university degree or its equivalent, one year's training may be remitted. A certificate will be granted after examination, and subsequent to a certain date, of which notice will be given, no uncertificated appointment of health visitor may be made by any local authority. Further details will be found in the documents to which a reference has been given. Restrictive in form only, the regulations are a charter for the approved health visitor which, by protecting her from unqualified competition, will afford a much needed stimulus to the supply of the better class of visitor. The Ministry of Health was bound to protect in this way one of its principal agents in health work, and has done well in making this reform its first public action.

## Annotations.

"Ne quid nlmis."

### BETTER INSURANCE PRACTICE.

THE Special Conference of Representatives of Local Medical and Panel Committees, convened in London on July 17th and 18th by the Insurance Acts Committee of the British Medical Association, was chiefly concerned with the conditions of service under the National Health Insurance Acts and with possible extensions of this service. Any discussion of the rate of remuneration of the panel practitioner for his services was expressly ruled out, the determining of the proper amount of the capitation fee per insured person being left for a future occasion. The basis of discussion was the long and closely reasoned report of 112 paragraphs issued by the Medical Department of the Association in May last for the consideration of panel committees and individually to every member of the medical profession, as well as the memorandum of discussions convened by the Insurance Commissioners, to which allusion was made in a leading article in our columns on June 14th. A summary of the report and its recommendations appears on p. 169 of the present issue. Report and memorandum together cover the whole field of insurance practice, and it speaks volumes for the foresight and dialectic skill with which they were drawn up that no considerable principle contained in them, and little even of detail, were overturned by a conference consisting of individuals deeply concerned to make the best of both the present and the future. Acceptance of an amendment standing in the name of Stockport opposing the limitation of individual panels of insured persons to 3000 was the nearest approach to an adverse vote. This amendment was carried by a small majority, but with the proviso, emanating from the London representatives, that the Panel Committee must accept the unpleasant duty of adjudicating the efficiency of any practitioner exceeding this limit when called upon to do so by an insurance committee. The conference set its face sternly against discouragement of large panels by any lowering of the capitation fee, holding that such a suggestion of reduction on taking a quantity was derogatory to the responsible and honourable character of panel practice. No one, however, had a word of condonation for the single-handed practitioners alleged to have more than 6000 patients on their lists. Necessitated, possibly, by war emergency such ill-directed ambition can hardly long survive the pressure of public opinion.

The question of the precise amount of the capitation fee being thus excluded, discussion centred round the provision of an adequate service under conditions agreeable and convenient alike to doctor and patient, assuming that—its scope being known—such service would be adequately remunerated by the Ministry of Health. In his opening address Dr. H. B. Brackenbury cited a few instances in which panel practice had recently not shown amenities to the insured person. It was difficult, he said, for the panel patient to obtain the administration of an anæsthetic when required for a minor operation, in certain areas he might have to wait in a queue to obtain advice and treatment at all; and if doubt should arise as to his being a panel patient, medical assistance might be

sought unavailingly in case of serious emergency. Panel practitioners are, we feel sure, as anxious as the Government and the public to obtain a medical service where these things do not occur. On the practitioner's side there is a widespread feeling, amounting to a sense of soreness, that certain special services which are the patient's right under the Insurance Acts are nevertheless outside the range of general practitioner treatment, and should not be demanded of him without special remuneration. Such services include, for instance, the administration of general anæsthetics, attendance at miscarriages, and possibly the treatment of fractures and dislocations, and visits paid at night. Existing regulations admit of these services being made a prior charge on the local medical fund. If this fund itself is sufficient—i.e., if the capitation fee is large enough—it is clear that a first charge on the general fund is as favourable a form of remuneration for special services as a special fund created for the purpose. No one contended that Parliament was likely to sanction an unlimited fund for this purpose, but the Stockport representative was able to show by actual figures that the amount of these special services rendered by practitioners in his district was strictly proportional to the special remuneration available, and not to the demand for such services. Abstinence from service where the demands are demonstrably unreasonable—which is not fairly to be called shirking, though the term is thus applied—cannot be regarded as an inherent sin of insurance practice; and the view expressed in the report of the Insurance Acts Committee finally prevailed, although by a hairsbreadth. Panel practice, it will be seen by this report, will not have the additional complication of special pools for special purposes. Thus many important matters seem to have been settled, but the real struggle will come with the fixing of the new capitation fee.

### THE CAIRO SCHOOL OF MEDICINE.

THE winter session of the School of Medicine at Cairo, under the Egyptian Ministry of Education, begins on Oct. 4th, and it is the intention of the Ministry to make the school at this crisis in the development of Egypt worthy of its great historical and ethnological position. The school was inspired originally by French surgeons of the time of Napoleon, and has occupied its present site since 1837. The existing hospital of 600 beds is housed in a building entirely inadequate for its purpose, and the school itself has to refuse two-thirds of its yearly average of 150 applicants, but the enlargement and remodelling of both are under contemplation by the Government of Egypt in association with the proposed foundation of a University. But the Egyptian Educational Mission is not willing to let the proper development of the school await any extensive scheme of rebuilding, and the all-important matter of an adequate teaching staff is being handled forthwith. Reference to our advertisement columns will show a number of vacant posts for which the combined annual pay is over £10,000. The Egyptian students have been out on strike since March 9th last, and there is a strong feeling amongst them that the staff should be recruited from men of Egyptian nationality so far as this is possible. For the present, however, there are no Egyptians with the necessary qualifications. The whole-time pro-

fessorship of surgery is an innovation and designed to attract someone who is keen on teaching and research. The professor of pharmacology will have hospital beds at his disposal and a free field for research in the treatment of Egyptian diseases, and occupants of these chairs will presumably become professors in the faculty of medicine when the University takes shape. The lecturer on pathology will have a specially attractive field of work open to him, for many pathological problems still await solution in Egypt. The lectureships are designed to encourage research among Egyptians, some of whom are already being trained in England. But we are informed that none of the appointments are earmarked for any local or other candidate. The selection will be made, in the first instance, by small expert boards in England, the final selection taking place in Egypt on the recommendations of these boards. We wish every success to this practical effort for placing medicine on a substantial foundation in Cairo.

#### THE AFTER-HISTORY OF WAR NEPHRITIS.

Merklen and Desclaux<sup>1</sup> examined 26 men who had been temporarily discharged from the Army for chronic nephritis one year previously, and summarised their observations as follows: 1. Six men had no albuminuria nor any signs of renal or cardiac disturbance. There was no rise of blood pressure, and the heart was of normal size on radioscopic examination. They might therefore be regarded provisionally as cured. 2. Three men showed cardio-vascular symptoms only, such as an increase in size of the left ventricle, accentuation of the second aortic sound, a high blood pressure, and palpitation. 3. Seventeen cases, or two-thirds of the total, showed various symptoms of chronic nephritis, and albuminuria was present in every case. Though it is impossible to form a general prognosis in nephritis owing to the variable character of the affection, the writers feel justified in concluding that at the end of a year the majority of men who have been discharged from the Army for nephritis will still present symptoms of the condition.

#### AN ANTHROPOMETRIC SURVEY.

THE data obtained by the late Ministry of National Service when examining recruits in regard to their fitness for a soldier's life are in the possession of the Minister of Pensions and, in reply to a deputation from the British Association, Colonel A. L. A. Webb, Director of Medical Services, stated on July 18th that the various regional reports had been arranged and would shortly be ready for publication. Measurements, such as height, body-weight, and chest perimeter, in relation to age and occupation, have great objective value, while other data are more or less vitiated by the personal equation of the recorder. Many attempts have been made to obtain simple criteria of working ability. As long ago as 1846 Mr. John Hutchinson read before the Royal Medical and Chirurgical Society a paper, fully reported in our columns at the time, dealing with a method of detection of disease by the spirometer. This engine long fell out of repute, but recently a definite minimum standard of vital capacity was set up as a condition of admission to the Air Force, and Professor Georges Dreyer laid stress upon this measurement in a paper read before an Inter-Allied Sanitary Congress of Aeronautics held at Rome in February last. A single observation of certain

anatomical and physiological data, carefully made and recorded, may have value when dealing with the population as a whole, but how much greater would be the value of continuous exact records, such as are now within the grasp of the Ministry of Health. The policy of the Insurance Commissioners has been to demand from its medical staff a number of entries so vast as to alienate most panel practitioners for all time from statistical method. These entries are recalled at the end of each year, thus rendering them unavailable for further reference. A tithe of this labour spent on a continuous record card would have produced results far exceeding in value those of the National Service inquiry. The panel conference, which we deal with elsewhere, had something of this possibility laid before it last week.

#### THE CEREBRAL COMPLICATIONS OF MUMPS.

THOUGH a typically harmless disease, mumps may rarely be attended by serious and even fatal complications. In the Index Catalogue of the Surgeon-General's Library six deaths from mumps are recorded. Death is probably always due to cerebral complications. About 150 cases of cerebral complications have been reported. In the *Archives of Internal Medicine* for June Lieutenant R. L. Haden, U.S. Army, has published nine cases which were observed at Camp Lee, Va., U.S.A., among 476 cases of mumps, and he has reviewed the literature of the subject. The nature of the cerebral complications has been much discussed. Before the advent of lumbar puncture it was considered as meningismus, but with demonstration of pleocytosis of the spinal fluid it was looked on as meningitis. In simple mumps, according to Doptier, the cerebro-spinal fluid is normal. Many things point to the conclusion that the lesion is an encephalitis and not simply a meningitis. In most cases the cerebral symptoms are out of all proportion to the meningeal reaction, as shown by the condition of the cerebro-spinal fluid. The common symptoms are high fever, headache, nausea, and vomiting. Usually there is only slight rigidity of the neck and Kernig's sign is not well marked. Numerous cases of involvement of the cerebrum alone are on record. In these there are no definite meningeal signs, and the cerebro-spinal fluid is normal. Among the symptoms observed in 31 cases reported by Acker were unilateral convulsions, monoplegia, hemiplegia, aphasia, disturbances of speech, psychoses, disturbances of sensation, and stupor. These point to affection of the brain substance. Other symptoms, such as bradycardia, headache, vomiting, and optic neuritis are probably due to intracranial pressure. The few necropsies recorded have shown congestion of the brain with only serous meningitis. In the nine cases reported by Lieutenant Haden the symptom-complex was fairly uniform. Usually as the parotitis was subsiding the temperature rose, with little change in the pulse-rate, severe headache, nausea, and vomiting. Often the patient had orchitis. On examination he was dull, answered questions slowly, showed slight stiffness of the neck, a suggestion of Kernig's sign, and variable reflexes. Lumbar puncture yielded clear fluid under increased pressure with lymphocytoses. In a few cases increased pressure was the only abnormality. Smears and cultures were made from the fluid in all cases, but in only one were organisms (Gram-positive cocci) found. Such cocci have been described by several observers as the organisms causing the disease, although a filterable

<sup>1</sup> Bull. et Mém. Soc. Méd. de Hôp. de Paris, 1919, xliii., 434-7.

virus has also been suggested. The fluid in this case was turbid. Lumbar puncture proved effectual therapeutically. The temperature usually fell quickly to normal and the headache was relieved. The following case may be taken as typical. A wagoner, aged 21 years, was admitted to hospital on Feb. 3rd, 1919, complaining of headache, swelling of the neck, and occasional nausea. Three weeks ago he first noticed the swelling. On admission the right submaxillary glands were swollen, the temperature and pulse were normal. On Feb. 5th the left parotid became swollen, and on the 9th bilateral orchitis was noted. On the 10th the patient became very dull and suffered from headache and vomiting. The temperature was 105° F. and pulse 180. On the 11th he was very drowsy and still vomiting. There was definite stiffness of the neck. The knee-jerks were not obtainable. Kernig's sign was positive and Babinski's negative. Lumbar puncture yielded clear fluid under increased pressure, and the patient's condition immediately improved. On the 13th the pulse was only 48 and the temperature subnormal. He said that he could not see well, and during the night became delirious. On the 14th he was stuporous with the head retracted; the pupils reacted sluggishly. The temperature was 97° and pulse 44. The deep reflexes could not be elicited. Next day he was much improved. Rapid recovery followed. The following were the laboratory findings: Feb. 12th, leucocyte count, 6200. Differential count: small mononuclears, 48 per cent.; large mononuclears, 6 per cent.; eosinophils, 5 per cent.; polymorphonuclears, 41 per cent. Feb. 11th, cerebro-spinal fluid contained 10 cells per c.mm., all mononuclears. Feb. 14th, the fluid contained only 5 cells per c.mm. Sugar was present on both occasions.

#### A FLOATING SCHOOL OF TROPICAL MEDICINE.

To most of us the stimulus of encouragement and criticism is necessary to bring forth our best, and the foregathering of workers on kindred subjects at the regular meetings of learned societies has often acted like the piece of leaven in the amorphous dough or, as we should now say, as a catalyst in a mass reaction. This stimulus has been wanting to most workers in tropical medicine, cut off for months or years from their friends and critics, and, in addition, borne down by conditions of great bodily discomfort. Small wonder that under these circumstances the best work has not always been done, although the history of tropical medicine is punctuated with individual brilliant successes. Nine years ago, in a letter to our own columns,<sup>1</sup> Dr. Andrew Balfour, struck with the usefulness of the Wellcome floating laboratory on the Nile, suggested the extension of the marine floating laboratory for the purpose of visiting any desired portion of the globe and bringing back a store of material for museum and teaching purposes. By such a perpetual *Challenger* expedition diseases could be studied on the spot, parasites observed in a living state, and tutorial classes given to successive crews of students desirous of obtaining a nearer insight into the fascinating problems of disease and its prevention in hot countries. Dr. Balfour's suggestion passed unheeded, and it remained for Dr. Louis Sambon, in a lecture delivered before the Royal Society of Medicine on June 14th last, by arrangement with the

West India Committee, to develop the theme of bringing students periodically into the tropics by means of a floating school. The islands of the Lesser Antilles, which he had recently visited, were ravaged each by its particular breed of epidemic, and nothing would coördinate the isolated efforts of medical officers on these lonely isles so thoroughly as a regular circulation of expert advice and help. He advocated a development on international lines, having already received encouragement from the French and Italian Governments. The idea thus timely set forth was not allowed to drop and came up for discussion at a private meeting held under the chairmanship of Sir Humphry Rolleston on Thursday, July 10th, at the same place. Here Dr. Balfour set out the views summarised above, adding the further claim of a floating laboratory as a link between the Dominions and the Mother Country. Sir David Bruce and Dr. G. C. Low, among others, doubted the feasibility of the floating school as a substantial agent of research, the latter pointing out that sleeping sickness and kala-azar at all events could not be studied on the littoral. The extended establishment of local shore laboratories appealed to the majority of those present for the purpose of actual research work, neither nostalgia nor rolling and pitching apparatus being specially conducive to the desirable mental detachment. Sir Thomas Horder voiced the general consensus in finding the floating school an attractive idea for teaching purposes, adding that finance should not be an impediment if the ruling authorities were satisfied of the practicable character of the proposal. A committee was appointed, with Dr. Balfour as chairman, and Dr. Low, Dr. R. T. Leiper, and Dr. Sambon as secretaries, to inquire into the question in all its aspects. We are inclined to agree with Dr. Balfour, who has from first to last been the moving spirit in the proposal, that the cost of such a floating school might reasonably be regarded by Parliament and public in the same light as polar expeditions. The adventures and prizes are much the same, the gain, indeed, presumably much greater: the difference consists chiefly in the substitution of pith helmets and mosquito nets for fur caps and mocassins. Within a generation, if ankylostomiasis and pellagra are not then extinct, we doubt not that the floating school will be a routine method of education and preventive study.

#### CRIME AND RESPONSIBILITY.

THAT "insanity is not an absolute defence," and that what is called the defence of insanity to the charge of murder requires, for success, not merely the proof of insanity, but that of insanity of such a nature as to carry with it irresponsibility to the law, is clearly shown by Section 2 (1) of the Trial of Lunatics Act, 1883, in which the following form of words is employed: "insane so as not to be responsible according to law for his actions at the time the act was done." Formerly, many judges refused in court to allow, when in murder cases the "defence of insanity" was raised, evidence to be given by experts as to the existence of insanity in the broad, or medical, sense; but nowadays practically every judge allows, as did Sir Charles Darling in the recent case of Perry, testimony of such nature to be given before attention is directed to the more stringent issue of legal responsibility. It is generally by the application of the M'Naughton Rules that this question of responsibility is decided, but there are not wanting judges who

<sup>1</sup> THE LANCET, 1910, ii., 55.

will direct, in accordance with the view of the late Sir James Stephen, that responsibility may be abrogated by loss of control, if arising from mental disease or infirmity, and not from the accused person's own conduct. Such elasticity is permissible in practice because, after all, the M'Naughton Rules are not part of the statute law which is applicable to civilians. In respect of military law it is otherwise. Reference to the "Manual of Military Law" (chap. vii., par. 9) will satisfy those to whom the point is unfamiliar that, in the case of a member of His Majesty's Army under trial by court-martial, the question of responsibility, if a defence of insanity be raised, can only be resolved by a rigid and undeviating application of the M'Naughton Rules. The effect of this is that when, either in the course of trial or afterwards, medical testimony is adduced, or a Medical Board is constituted to inquire into, as is said, the state of mind of the accused, the medical witnesses are required to testify, or the Board to direct inquiries, not to the general question of the accused's sanity or insanity at the time of inquiry or anteriorly, but to the specific questions implied in the Rules. All other considerations are irrelevant; the problem is simply whether or no it can be said, at a certain date, that a certain person was, at an anterior date, in such a state of mind that he did not know the nature and quality of his act or that what he was doing was wrong. There is no room for elasticity of interpretation; and the question of impulsion, or lack of control, cannot be raised. That this is a perfectly fair representation of the procedure in vogue is known at any rate to some of those who have lately served overseas; and official confirmation is afforded by the answer given by Mr. Macpherson, in the House of Commons on April 11th, 1918, to a question put to him some time previously by Sir William Job Collins.<sup>1</sup> No great effort is required, then, to realise how readily the specific instructions addressed to a Medical Board may determine the infliction of the last penalty upon an officer or man who, under the influence of temporary mental disorganisation produced by physical agencies, commits the supreme military offence of "desertion in the face of the enemy," or of apparent cowardice. The military necessity for such stringency is not a matter on which we express any opinion; but the facts are as stated. The ultimate consequence to Perry, alias Beckett, of his acts has been his execution; but he enjoyed more generous opportunity under the English common law than would have been his had he left a post of military duty under that kind of mental compulsion best known to those who have experienced—or feared it.

#### THE SUPPLY OF DRUGS DURING THE WAR.

A VERY interesting Memorandum was issued from His Majesty's Stationery Office this week (Cmd. 183) on the special measures taken by the National Health Insurance Commission (England) in relation to the supply of drugs and other medical stores during the war. It shows how the critical position in regard to the supply of drugs created by the sudden and unexpected outbreak of war was dealt with. Immediate steps had to be taken to conserve existing stocks and to encourage the production in this country of drugs for the supply of which we had hitherto been wholly or mainly dependent upon

enemy countries. Conspicuous service was rendered by the Royal Society, while the energy and enterprise shown by the chemical manufacturers of the country will lead to permanent results of the utmost importance to the medical needs of the community. The requirements of the Forces and of the civil population were met after a little inevitable shortage experienced at the beginning. The Chairman of the Committee, Mr. Waldorf Astor, concludes his prefatory note by saying that the fine chemical industry has been very greatly developed and extended, and that this country is now capable of manufacturing on a large scale all the important medicinal chemicals which before the war were practically a German monopoly. Thus ground has been regained which should, in point of fact, never have been lost. The Memorandum, opportunely enough, provides a key to many of the scientific products now being exhibited by the British Science Guild at the Central Hall, Westminster.

#### HUGH OWEN THOMAS.

THE Medical Institution of Liverpool have organised a scheme for the perpetuation of the memory of Hugh Owen Thomas, a pioneer worker in orthopædic surgery. Hugh Owen Thomas was born in 1834 and studied medicine at Edinburgh in the days of Goodsir, Syme, Spence, and Simpson, with Turner as demonstrator of anatomy. Later he entered University College, London, and qualified as a Member of the Royal College of Surgeons of England in 1857. On returning to Liverpool he took up surgical work in connexion with workmen's societies and at the docks, his practice being almost entirely concerned with accidents, deformities, and joint diseases. He instituted a free clinic at his surgery on Sundays—a recognised practice before the establishment of out-patient departments at the hospitals—and devised and made his own splints, employing a blacksmith and various artisans in their construction. Later he himself became an expert metal-worker, laying great stress on the careful fitting of all splints and their correction from time to time under his own supervision. In 1871 he described an ingenious method of wiring fractures of the lower jaw, and soon afterwards published an important work on the treatment of the diseases of the hip, knee, and ankle joints. The appliances which he invented have not been improved upon in principle, and in joint diseases his splints enable sufferers to enjoy fresh air and exercise, as they did upon their invention half a century ago. He was without doubt one of the founders of modern orthopædic surgery, and the appeal for funds to endow a worthy memorial to his work in the city where his whole life was spent should certainly meet with a generous response. Subscriptions should be sent to Major C. Thurstan Holland, at the Medical Institution of Liverpool, and crossed "Hugh Owen Thomas Memorial."

THE House and Library of the Royal Society of Medicine will be closed during the whole of August for repairs and cleaning.

A DINNER will be held in London, at a date to be arranged, for all R.A.M.C. (T.F.) officers; will those who are interested and would be likely to attend kindly communicate with Lieutenant-Colonel A. R. Henschley, D.S.O., R.A.M.C. (T.F.), care of Holt and Co., 44, Charing Cross. It would facilitate matters if London officers would say whether they would kindly serve on the committee.

<sup>1</sup> THE LANCET, 1918, i., 587.

## THE AMERICAN HOSPITAL FOR GREAT BRITAIN.

THE American Hospital for Great Britain, to which allusion has been made frequently in our columns, was formally founded on Thursday, July 17th, at a meeting at the House of the Royal Society of Medicine.

LORD READING, the Lord Chief Justice of England, presided over the meeting of supporters of the hospital, and in a brief but happily worded speech laid stress on the coöperation that had existed between Americans and British during the later stages of the war. He pointed out that from the very beginning of the war a certain number of American medical men had worked in British hospitals, and that out of the cordial relations thus established had arisen the idea that there should be founded an American hospital in London both for the reception of sick Americans, and to act as a centre for post-graduate work in London among Americans who hitherto have pursued such studies mainly in Berlin or Vienna.

MR. PHILIP FRANKLIN, who has been a moving spirit in the foundation of the American Hospital for Great Britain, then made a statement in which he pointed out the need for an American Hospital in London, which the American medical man could make his headquarters when engaged in organised post-graduate work.

In the absence of the American Ambassador, Mr. NEWTON CRANE moved, and Sir W. ARBUTHNOT LANE seconded, the following resolution:—

"That, in commemoration of the coöperation of the medical men of the United States and of Great Britain during the European War, and to strengthen the friendship existing between the two nations, the American Hospital for Great Britain be, and is hereby, founded for the medical and surgical treatment of patients of all classes, irrespective of creed or nationality, and for the promotion of scientific study and research."

Sir HUMPHRY ROLLESTON, President of the Royal Society of Medicine, then moved a resolution that a governing body should be constituted. Sir JOHN BLAND-SUTTON seconded and paid an eloquent tribute to the value of the work done by lay boards in administration hospitals.

The following were constituted the original members of the council:—

His Excellency the American Ambassador.	Mr. Robert Grant, jun.
Mr. Walter Blackman.	" James Benson Kennedy.
" George M. Cassatt.	" J. Blair MacAfee.
" R. Newton Crane.	" George A. Mower.
" Wilson Cross.	" Francis E. Powell.
" James E. Dunning.	" H. Gordon Selfridge.
" J. Grant Forbes.	" Henry E. Stoner.
" Philip Franklin.	" Lawrence L. Tweedy.
" Clarence Graff.	" F. C. Van Duzer.
	" E. Bradner White.
	" Robert Skinner.

MR. F. E. POWELL moved, and Mr. WALTER BLACKMAN seconded, a resolution, which was unanimously adopted, constituting the Medical Committees in Great Britain and in the United States, the following being the selected personnel:—

Of the Medical Committee in Great Britain:

Sir William Osler, Regius Professor of Medicine, University of Oxford.

Sir W. Arbuthnot Lane.

Sir Humphry Rolleston, President of the Royal Society of Medicine.

Sir John Bland-Sutton, Vice-President of the Royal College of Surgeons of England.

Mr. J. Y. W. MacAlister, Secretary of the Royal Society of Medicine.

Mr. Philip Franklin, Joint Honorary Secretary of the Fellowship of Medicine.

With power to add to their number.

Of the Medical Committee in the United States:

Dr. George W. Crile, of Cleveland, nominated by the

American Academy of Science on International Relations.

Dr. W. J. Mayo, of Rochester, Minnesota.

Dr. Charles H. Mayo, of Rochester, Minnesota.

Dr. Albert J. Ochsner, of Chicago.

Dr. Rudolph Matas, of New Orleans.

Dr. Franklin Martin, of Chicago, nominated by the

American Gynaecological Association.

With power to add to their number.

Mr. Philip Franklin was then unanimously appointed honorary secretary to the hospital, while it was left in the hands of a small subcommittee to invite the support of certain vice-presidents. The committee also decided to appoint legal, financial, and appeal committees. The meeting terminated with a cordial vote of thanks to the Royal Society of Medicine for its hospitality and assistance to the movement.

In replying, Sir HUMPHRY ROLLESTON wisely took the opportunity of pointing out that this movement was in no sense in rivalry to the existing post-graduate work in London, but would prove a source of support and inspiration of such efforts.

## THE MINISTRY OF HEALTH: ORGANISATION OF MEDICAL STAFF.

ON the establishment of the Ministry of Health the medical staffs of the Local Government Board and of the National Health Insurance Commission have been brought together to form the main portion of the medical staff of the Ministry, but on a newly organised system, and with considerable additional posts.

The Minister has appointed Sir George Newman, K.C.B., as Chief Medical Officer of the Ministry, with status corresponding to that of a secretary of the Ministry. By arrangement between the President of the Board of Education and the Minister, Sir George Newman retains his position as Chief Medical Officer of the Board of Education.

Five new posts of "Senior Medical Officer" have been established, with status corresponding to that of Assistant Secretary. To these the Minister has appointed the following:—

Dr. G. S. Buchanan, C.B.

Dr. Janet M. Campbell (who will also by arrangement with the President of the Board of Education act as Chief Woman Medical Adviser of that Board).

Dr. F. J. H. Coutts.

Dr. A. W. J. MacFadden, C.B.

Mr. J. Smith Whitaker (who will also act as Medical Adviser to the National Health Insurance Joint Committee).

The whole of the rest of the established medical staff of the Ministry will be in one grade, to be known as "Medical Officers." They will comprise the remainder of the existing medical staffs of the Local Government Board and of the Insurance Commission, with the addition of new officers still to be appointed as the additional services may require. The following appointments have so far been made:—

Dr. Irene Cecil Davy Eaton.

Mr. Major Greenwood (Medical Statistics).

Dr. Florence Barrie Lambert (Remedial Treatment).

Dr. Jane Holland Turnbull, C.B.E. (Obstetrics and Gynaecology).

Besides this regular staff, arrangements have been made whereby the Ministry may secure the services, from time to time, of specialists and others on a part-time basis; amongst these are included at present the following:—

Dr. Maurice Craig (Psychological Medicine).

Colonel L. W. Harrison, D.S.O. (Venereal Diseases).

Sir David Semple (Rabies).

Further appointments will be announced as they are made.

PORTSMOUTH AND SOUTH HANTS EYE AND EAR HOSPITAL.—At the annual meeting of this institution, held on July 14th, it was reported that overtures had been received from the Royal Portsmouth Hospital with a view to amalgamation, but that the committee had not felt justified in altering the present arrangements. The financial statement showed a small deficit of £148 on the year's working.

PRESENTATIONS TO MEDICAL MEN.—On the occasion of the closing of the Hart House V.A.D. Hospital, Burnham, Somerset, Dr. N. O'Dell Burns, the honorary medical officer in charge, was presented with a silver cigarette case as a mark of respect and esteem.—Dr. W. R. Newton Cole, St. Tudy, Cornwall, has been presented with a clock and an album containing the names of 300 subscribers, as a mark of respect and esteem, on the occasion of his retiring from active work after 37 years' residence in the village.

## WOMAN IN INDUSTRY.

## I. WOMAN'S ECONOMIC VALUE IN RELATION TO HEALTH.

THE ability of women to compete on equal terms with men in industry and the principle of "equal pay for equal work" is very fully discussed in the Report of the War Cabinet Committee on Women in Industry, which has lately been published. Dr. Janet Campbell deals with the Health of Women in Industry, and in her memorandum brings out important points with regard to men's and women's work which, although well-known to physiologists and students of industrial medicine, have, so far, not been given sufficient prominence in actual practice. No one has ever denied that a woman is handicapped on account of her potential motherhood, but this handicap is, as a rule, far greater than is necessary. Those who are engaged in looking after the health of girls employed in offices must have realised that much of the tribulation and inability to carry on which occur at the menstrual periods is avoidable, and is much increased by ignorance of the elements of hygiene and the laws of health. Decayed teeth are only too common among all classes of workers, the constipation of women is proverbial, digestive disturbances are not unusual, anæmia is essentially an ailment of girls and young women, and it is a well-known fact that girls and women often forego proper meals. All this tends to a lowered state of vitality, which is still more accentuated during menstruation.

*Disadvantages of Women Workers as Compared with Men.*

Only in very rare and exceptional cases is it possible to compare with any degree of fairness the ability, both physical and mental, of men and women. Their upbringing has been different and their training and development have been forced along different lines. Among the children of the poor the boys, during out-of-school hours, are given the open-air work to do, such as carrying messages, &c., whilst the girls are cooped up indoors helping with the domestic work. Teachers in secondary schools complain that it is impossible to send a girl up for a certain examination at the same age as a boy. She is usually about a year behind, not, as they say most definitely, on account of her lower mental capacity or of an even slightly lower grade of intelligence, but because she has no proper time for her home work and because, being engaged in household tasks, she comes to school with her brain more tired, her mind less receptive, and her memory less retentive. The same handicap follows her through life. If she is living at home and going out to work there are still household duties which she is expected to carry on, although nothing of the kind is expected from her brothers. In the poorer classes, as a mother of a family compelled to go out to work, it is still her duty to keep the home, cook the meals, and do the family washing. A dish for the dinner is unusual, as it means more washing up, so the mother spends her time going backwards and forwards from the fireplace to the table helping the rest of the family to food. She herself has for her dinner "whatever is left," and this occurs as a matter of course. There seems no doubt that less and poorer food, combined with domestic duties, has an extremely deleterious effect on women's work, and handicaps them to a very marked degree in competition with men for work and wages. Miss Anderson, in her evidence before the Committee, pointed out that "a limitation of hours was necessary in the national interest, in order to enable women with domestic responsibilities to carry on their home duties." Miss Martindale "showed that night-shifts, and especially permanent night-shifts, are particularly harmful to women with domestic responsibilities, as it is more difficult for them to obtain adequate sleep; they invariably do their own housework during the day and their rest is subject to continual interruptions; their work becomes inferior in quality and their health suffers." There are no doubt profound physiological differences between men and women, as Dr. Campbell insists, but there has been no proper evaluation of these differences, and until the question has been more fully elucidated there is no reason to conclude that women's handicaps are physiological and unalterable. A great difficulty arises in the case of the married woman who has a baby and who has to add to the family income. For the national welfare the baby should be breast-fed; for

the family welfare the mother must go to work. It seems to us that the only way out of the difficulty is the institution of creches in connexion with the factories where nursing mothers are employed, which should be under the supervision of the doctor who is also in charge of the health of the mothers, and where time should be allowed every four hours for breast-feeding.

*An Old Problem in a New Aspect.*

These are some of the more obvious considerations that arise on a first survey of the report, but they lie at the root of the whole of social and industrial medicine. They are the justification for the call for more effective supervision and for energetic research into the causes of industrial fatigue and the methods of preventing disease directly or indirectly due to occupation. Employers of the more educated type of labour do already to some extent provide efficient supervision, preliminary medical examination, and medical advice. But such conditions as decayed teeth, unhealthy throats, and defective eyesight usually remain unrealised and untreated among employees of the poorer classes. It what follows the vast problem of industrial health from the woman's point of view is studied largely in Dr. Campbell's own words.

## II. THE PERSONAL HEALTH OF THE WOMAN WORKER.

In her memorandum on the Health of Women in Industry, included in the Report of the War Cabinet Committee on Women in Industry, Dr. Janet Campbell points out that in considering the position of women in industry and their capacity and power of continuance to compete equally with men two essential principles can never be disregarded, namely: (1) the profound physiological differences between the man and the woman; and (2) the woman's potential function of motherhood and child-bearing. The woman's abdominal muscles are longer, and, as a rule, less well developed; they act under greater mechanical disabilities on account of the relatively greater length of the abdominal cavity, the greater area of the abdominal wall, and the larger size of the pelvic cavity. This natural weakness is not infrequently accentuated by habits of dress and by lack of proper use and training of the muscles. The effect of pregnancy, especially when repeated, is usually a further weakness and stretching of the abdominal walls, which result in a less effective support of the internal organs. The muscular system of the girl and young woman can be greatly developed by suitable nutrition and training, but, in this country at any rate, the smaller size of the bones, together with the mechanical disadvantages of the general build and an inherent physiological difference not to be overcome rapidly, if at all, by any method of upbringing, make it unlikely that women can become equal to men in physical strength, and suggest that uncontrolled competition between men and women in matters requiring considerable muscular energy is undesirable. The greater weight of the man is itself an advantage where heavy work is concerned, and the strength of his muscles and joints makes him less liable to instability or accident from sudden or violent jerks or strains.

Owing possibly to the greater fineness and delicacy of her skin and the greater deposit of adipose tissue, a woman usually reacts more quickly than a man to an unsatisfactory atmospheric environment, and particularly to ill ventilation and high temperatures. She loses heat from the surface of the body less rapidly than the man, and therefore feels low temperatures less and high temperatures more.

There seems no reason to believe that the *special senses* of a woman (sight, hearing, touch, taste, smell) cannot be trained as highly as those of a man, though there may be certain differences in the two sexes. As regards the *central nervous system*, there is probably little difference, except as regards a woman's higher degree of emotional expression. Professor Sherrington stated that, judging by certain simple sensory tests, the young woman's delicacy of sensation is possibly less than the young man's, but the more complex the test the smaller the difference.

*Maternity.*

The function of maternity, even when potential only, necessarily imposes on the woman disabilities from the point of view of physical strength and efficiency. The structure of her body is framed with a view to pregnancy and childbirth, and is less well adapted to muscular exertion

than that of the man; she is further subject to periodical functional disturbances which tend to render her nervous and muscular energy somewhat unequal and varied. Interruption of employment due to childbearing and lactation is an economic handicap to the married woman; pregnancy places a considerable physiological strain upon the general metabolism which requires adequate physical compensation if the woman is to maintain her health and strength. She is also exposed during this period to various dangers, some of them chiefly physiological in origin, others due to more or less unsatisfactory treatment at the time of her confinement, but the results of which may persist as permanent disabilities and render her less fit for her ordinary occupation and less able to resist subsequent strain or fatigue.

#### Nutrition.

One of the primary requirements for healthy physiological development is satisfactory nutrition.

The habit of the woman is to consume less than the man even when ample food is available; this habit is far more marked among working-class women and girls, who are frequently not in a position to provide themselves with an adequate diet. The average wages earned by women before the war made it impossible for them to procure good and substantial food; their diet, besides being less in quantity, was less satisfactory in quality than the diet of men in their own position. It is a matter of common knowledge that the mothers of working-class families often suffer from an inadequate diet; when the wages are insufficient the needs of the father as bread-winner almost necessarily come first, those of the children next, the mother's last.

*Fatigue*, the true index of which is diminished capacity, results in reduced output, even before it is observed subjectively by the worker. Persistent fatigue, shown in reduced physical capacity, results in the loss of resistance to disease or an unsatisfactory environment, which are further reflected in returns of sickness, of broken time, and of the number of accidents recorded. Fatigue naturally occurs earlier in under-paid, under-fed persons; the secondary results of overstrain, including sickness, are most common and excessive among this class of worker, which is mainly comprised of women and girls. It is a frequent cause of complaint that women workers are worse time-keepers than men; omitting such reasons as domestic duties and temporary physiological incapacity, fatigue, whether giving rise to actual sickness or not, will inevitably tend to increase absence and unpunctuality. Accidents have been shown to be most common during the period of the day when fatigue is most pronounced and to be due, in some degree at any rate, to diminished capacity leading to inattention and carelessness.

*Prolonged standing* is a not uncommon cause of excessive fatigue in women. Women who have borne children are likely to suffer more from continual standing than unmarried girls, and are more apt to develop varicose veins, internal displacements, or other disabling conditions in consequence. In order to avoid unnecessary fatigue and conserve physical energy, it is important that suitable seats should be provided for women engaged in occupations involving constant standing, even if occasional advantage only can be taken of them.

*Lifting heavy weights* is another source of overstrain and possible injury. Women are less able to lift weights than men, but are usually better able to deal with small compact objects than with bulky articles of the same weight. Part of their natural disability can be overcome with training, and in certain factories selected women have shown themselves surprisingly competent in the handling of heavy weights.

*Anæmia* is present in greater or less degree in a very large number of working girls. It certainly reduces their efficiency, sometimes to a considerable extent, hinders their full physiological development, and may predispose to more serious diseases.

*Overstrain* also results in greatly reduced industrial efficiency. The over-tired woman performs her task at an excessive expenditure of nervous energy. If long continued, this results in a serious lowering of vitality and the power to resist disease (for example, tuberculosis, infectious diseases, &c.), it renders her less capable of performing maternal functions such as nursing her baby, and it prematurely wears her out and makes her an old woman

long before her time. Overstrain may result from the nature of the work alone, but is far more likely to be associated with undue speeding up or competition with physically stronger workers of either sex.

*Incidence of sickness.*—The operation of the National Health Insurance Act revealed for the first time the remarkable incidence of minor and major sickness among girls and young women, an incidence which compared most unfavourably with the sickness rates for men. The report of the committee appointed to inquire into the alleged excessive claims in respect of sickness benefit contains important evidence in this connexion. This chronic ill-health among working women was ascribed to low wages resulting in badly prepared and insufficient food, and to conditions of employment, such as long hours, long standing, lack of fresh air, and long intervals without food.

Dr. Benjamin Moore, in an article on factory and workshop conditions and the prevalence of pulmonary phthisis, has pointed out<sup>1</sup> that after the thirtieth year there was a great preponderance of the disease among urban males which is not shared by urban females, no such disparity being observed between rural males and rural females. This is ascribed to the daily occupation—(1) the long-continued strain of work under unhealthy conditions, and (2) the infection of men (thus reduced in resisting power) by fellow workers actually at work alongside them while suffering from open phthisis. Since 1914 the mortality rate among urban women has shown a substantial increase. This, Dr. Stephenson thinks, may well be due to the introduction of many thousands of women into industrial life.

#### III. THE EFFECT OF INDUSTRIAL EMPLOYMENT ON MOTHERHOOD.

It is difficult to determine the effects of employment on the function of motherhood. As Dr. Campbell says, "It may be personal and physiological, but it is difficult to separate this from social and national welfare."

The direct result upon the reproductive system of the woman is probably largely negligible, except in the case of multiparous women engaged in heavy or fatiguing work. The influence of employment in causing an impairment of the general health and vitality is certainly, if indirectly, considerable. The effect of the increasing employment of women on the birth-rate has probably been to accelerate somewhat the steady decline which has been observed since 1876, and the figures relating to occupations in which married women's labour is common suggest that this result would become more pronounced if the proportion of employed married women was much increased. The influence of employment upon the infant mortality rate is not altogether clear. The industry associated with the highest infant mortality rate is mining, in which there is little employment of married women, but the housing and sanitation are notably inferior and the standard of general hygiene and domestic comfort is low. Almost as high infant mortality rates are associated with the pottery and textile industries, in which many married women are employed for long hours away from home. The regular employment of the mother necessarily deprives her infant of its natural food, which is the greatest safeguard to its healthy growth and development, and also of the careful and constant attention which is so necessary to its successful nurture. On the other hand, poverty or an insanitary environment may have an even more injurious effect than the mother's absence. This is borne out by the low infant mortality rates in 1916 and 1917, years during which a continually increasing number of married women was being employed. The infant mortality rate has shown its most rapid decline in the last decennium, during which industrial employment of women has increased. In 1899 the infant mortality rate for England and Wales was 163; in 1902 it was 133; in 1908, 120; in 1911, a year of heat and drought, it was 130, but dropped in the following year to 95. In 1915 it rose to 110, but in 1916 it was 91, the lowest recorded rate. In 1917 it again rose slightly to 97, but there has been no substantial interruption in the steady downward tendency. The chief direct causes of deaths amongst infants are: (1) premature birth, atrophy, marasmus, and congenital defect; (2) diarrhoea and enteritis; (3) bronchitis and pneumonia.

Among the various general influences which affect infant mortality, the most important would seem to be poverty,

<sup>1</sup> THE LANCET, Nov. 9th, 1918, p. 618.

bad housing and insanitation, the lack of education of the mother, and the occupation of the parents. Poverty and bad housing are often inseparable; ill-paid work and a low standard of domestic hygiene are usually, though not always, associated. A hand-fed baby is much less likely to thrive in such circumstances than in a well-to-do household.

*Parental Occupation and its Effect on Infant Mortality.*

With regard to the effect on the infant mortality rate of the occupation of the parents, it is shown that the mortality in the middle classes is only 61 per cent. of the total infant mortality of the country, which suggests that practically 40 per cent. of the mortality could be avoided if the health conditions of infant life in general could be approximated to those in the middle class. The observation is not a new one, for in the classic inquiry carried out by Sir John Simon and Dr. Greenhow for the old Board of Health, in the middle of the last century, into the sanitary state of the people of England, it was noted that one of the causes of the high rate of infant mortality then existing was the occupational differences among the inhabitants in certain large towns where women were greatly engaged in branches of industry away from home. In such circumstances the houses were usually ill-kept, and infants who should have been on the breast were improperly fed, starved, or quietened with opiates. After consideration of subsequent investigations in England and Scotland by other authorities, including the Home Office inspectors, Sir George Newman ("Infant Mortality," 1906) concludes that in towns where women are largely employed in factories, the disadvantages to the health and life of their infants are enormously increased on account of: (1) the injuries and diseases to which women and girls in factories are liable; (2) the strain and stress of long hours of hard work to the pregnant woman; and (3) the absence from home of the mother and the infant. The results of an investigation of Dr. J. Robertson, of Birmingham, carried out in two wards where the wages were low and the industrial employment of women was common, suggest that poverty was more injurious to infant life than the employment of the mother. Dr. G. Reid, medical officer of health for Staffordshire, in his report for 1910, shows that the infant mortality rate was greatest and had declined least in the five large towns in the county having the highest proportion of married and widowed women industrially employed. Industrial employment of women leads to the neglect of breast-feeding, and the infant may be left in the charge of an unskilled "minder" instead of being sent to a properly managed crèche. As a result epidemic diarrhoea and nutritional disturbances are more common, the infant's chance of survival during the first years of its life are diminished, and its liability to subsequent weakness and debility are increased. The areas in which the infant mortality rate is highest are the mining and manufacturing districts. In the mining districts the cause is probably to be found in defective housing and sanitation, overcrowding, and the low standard of general hygiene. In the pottery and textile trades it is probably due to low wages and the handling by the mothers of a substance specifically dangerous to infant life—namely, lead.

Married women's labour must be regarded from various points of view: (1) the direct effect on the health of the mother while she is bearing or nursing a child; (2) the general effect on her health in view of her domestic responsibility and duties; and (3) the effect on her home and children.

Besides its effect on the birth-rate and on infant mortality, the employment of married women may react directly on the personal health of the expectant and nursing mother, and on her general physical strength at other times by imposing a double burden of factory labour and domestic duties, while lack of "mothering" may lead to the moral and physical injury of the children. Employment under suitable conditions is not in itself injurious to the pregnant woman, while the money thus earned may enable her to be properly fed—a matter of the highest importance. If the work causes undue fatigue or involves strain or violence it may give rise to general or local injury and lead to premature confinement or complications of pregnancy. Section 61 of the Factory and Workshops Act, 1901, provides that a woman shall not return to work within four weeks of giving birth to a child and is generally observed, because most women do not desire to return to work until at least a

month, and usually longer, after their confinement. It would be undesirable to extend this period unless grants in aid were available to assist the mother.

*Wages in Relation to Health.*

The results of employment of women under war conditions have emphasised the important to health of the good food, clothing, and domestic comfort which can be obtained when the wages represent a reasonably adequate recompense for labour. They have also proved that properly nourished women have a much greater reserve of energy than they have usually been credited with, and that under suitable conditions they can properly and advantageously be employed upon more arduous occupations than has been considered desirable in the past, even when these involve considerable activity, physical strain, exposure to weather, &c. Light sedentary occupations are not necessarily healthy occupations. The commercial futility of unduly long hours of work and of overtime has been demonstrated repeatedly, together with the benefit to health and to output of shorter hours, of the abolition of work before breakfast, and of properly arranged spells and pauses. There is advantage to the employer as well as to the workpeople in the provision of factory canteens, well-equipped surgeries and rest-rooms, suitable arrangements for sanitation and hygiene, and, when necessitated by the nature of the work, of protective clothing.

*Physical Strain on the Worker with a Family.*

Dr. Campbell points out the great physical strain which is placed upon the woman who is industrially employed and also has a home and family to manage. This strain is often unrealised because the woman shoulders this heavy burden patiently as a matter of course and without complaint. That she is often surprisingly successful, though at the expense of her own youth and physical vigour, is no reason why the nation should be content to allow its mothers to wear themselves out in a life of colourless drudgery and a continual struggle with difficulties which frequently prove too great to be overcome, and of the results of which there is ample evidence in the sickness returns under the National Health Insurance Act. In addition to the general physical strain, a woman who has had children is more liable than one who has not to various forms of injury and disability arising from heavy work, work involving constant standing and so forth. Pathological conditions following upon confinement are likely to be accentuated and prolonged by certain forms of factory work. In such circumstances it is not possible for a woman to give her children that care and attention which are needful for healthy physical development and for the prevention of avoidable defects and ailments, or to make her home as pleasant, comfortable, and hygienic as she would otherwise do.

(To be concluded.)

## INSURANCE ACTS COMMITTEE OF THE BRITISH MEDICAL ASSOCIATION:

### REPORT ON THE REVISION OF THE CONDITIONS OF SERVICE.

THE report on the revision of the conditions of service under the National Health Insurance Acts and on possible extensions of service, drawn up in May last and circulated for discussion by local medical and panel committees, was passed substantially as presented by the Special Conference held at the Connaught Rooms, London, on July 17th and 18th:—

*Summary of the Main Changes.*

A summary of the main changes that would take place in the present terms and conditions of service in the event of the suggestions contained in the report being carried into effect, was included in the report as follows:—

- (i.) The central pool for the year would be actuarially fixed before the beginning of the year and the amount payable for the year to the practitioners collectively of each area (the local pool) would be known before the work of the year was commenced.
- (ii.) The distribution of this known amount would be made to practitioners definitely quarter by quarter soon after the work of the quarter was completed.
- (iii.) A first charge on the local pool would be the payment of an agreed fee in every area for the administration of general anaesthetics, and a second charge, if the practitioners of any area so wished, would be the payment of an agreed fee for attendance at miscarriages or for any one or more of a number of other specified special services.

(lv.) The distribution of the remaining portion of the local pool would then be made to practitioners in amounts proportionate to the names on each list, subject to some minor variations in the values to be attached to some names to meet special cases.

(v.) The present calculations and accounts for temporary residents and other like classes would be done away with, the payments for these classes being secured in the general distribution.

(vi.) The practitioners of an area would have no financial interest in the amount of the drug fund, the responsibility for any deficit in which would be assumed by the Treasury, but from the drug fund two payments would be made to all practitioners: (a) a small capitation fee, uniform for the whole country in respect of drugs supplied in emergencies; (b) a capitation fee, which might be variable from area to area or from practice to practice, in respect to dressings.

(vii.) Rural and semi-rural practitioners in every area would receive, in addition to the foregoing: (a) a payment from the drug fund in respect of patients for whom they dispense, fixed yearly on such a basis as to secure that the remuneration would be equal in every relevant respect to that of the pharmacists; (b) a payment from a special mileage or travelling fund calculated according to data, which would aim at securing for them an amount corresponding as nearly as possible to the excess cost of the necessary travelling (including extra time spent) over that of an urban practitioner.

(viii.) There would be a high limit—say, 3000—fixed for the whole country, beyond which no practitioner would be allowed to accept names on his list; but this limit would be for individual practitioners only. Every opportunity would be afforded for arrangements in the nature of partnership or assistantships, and, in the case of practitioners whose lists were above the prescribed limit on the day on which the limitation became operative, a period of one year would be allowed for the required reduction of the list, the practitioner himself having a voice in the exact method by which the reduction should be effected.

(ix.) It would be possible for a practitioner to come on the panel of an area under a special arrangement by which he would be guaranteed a small minimum payment for a period of two years, irrespective of the number on his list, provided that he undertook certain special obligations.

(x.) The machinery for keeping lists would be in some respects altered so as to eliminate the causes of some of the errors that have hitherto prevailed; at the same time the necessity for minute correctness would become relatively less important than hitherto.

(xi.) The present agreement between the practitioner and the Insurance Committee would be abolished, and the contract would take the form of a letter from the practitioner accepting the published terms and conditions.

(xii.) Specific arrangements would be made by which a practitioner could conditionally charge a fee (a) in cases in which there is a doubt as to whether the patient is entitled to medical benefit; (b) in cases where the service to be rendered is alleged to be outside the scope of medical benefit, but in which the practitioner claims to be specially qualified to render it, the amount of the fees in each case being deducted from subsequent payments to the practitioner should it be determined that the treatment was, in fact, due under the contract.

(xiii.) It would be permissible for a practitioner to arrange with fellow practitioners to undertake on his behalf certain kinds of treatment which, though within the scope of the contract, he was not, in fact, in the habit of undertaking in the case of his private patients—e.g., minor surgical operations.

(xiv.) The requirements with regard to (a) attendance on an insured person in an emergency; (b) the provision of a deputy during absence; (c) adequate surgery and waiting-room accommodation; (d) the maintenance of a satisfactory standard of competence as well as of conduct, would be strengthened.

(xv.) The arrangements for records and for certification would be revised with a view to making them less laborious and more useful.

(xvi.) Certain additional services would be established—e.g., consultations and specialised treatment, laboratories—and the arrangements with the tuberculosis service would be reviewed; in every case the general practitioner would have duties in connexion therewith; and he would be encouraged to associate himself with the work thereof; and he would have the right, if possessing the necessary special qualifications, of being appointed to give the service in the same way as a consultant or specialist.

(xvii.) Medical referees would be appointed with responsible duties, which would include their acting indirectly in a supervising capacity over the administration of the clinical services.

(xviii.) The machinery for dealing with alleged breaches of agreement would be made more clear, and alterations would be made so as to remedy some points which appear inequitable to practitioners.

The limitation of the number of the panel list was defeated at the Conference, the division being a close one.

#### Recommendations.

The following definite recommendations were appended to the report:—

(I.) That, subject to a full consideration of any suggestions from Local Medical and Panel Committees or from the Group Conferences, and subject also to any resolutions of the July Conference, the Insurance Acts Committee be authorised to negotiate definitely with the Central Government Department for new terms and conditions of service for 1920 on the lines of this report and of the two interim reports already issued.

(II.) That the Insurance Acts Committee be requested throughout such negotiations to keep in touch with Local Medical and Panel Committees and with other professional organisations with a view to a decision at the October Conference on the question of the amount of remuneration which practitioners would agree to accept for the services to be rendered.

(III.) That as regards the additional services for insured persons suggested in the report, it is important that, as from early in 1920, these services should be regarded as an essential part of the whole service, though in practice they might be developed only gradually.

(IV.) That the Ministry of Health should consider as soon as possible through its Medical Consultative Council the order in which and the method by which such services should be extended to the non-insured population; but that in this connexion it is essential (a) that a general practitioner service should be established for any class of persons before

such additional services are made freely available for that class; (b) that general practitioners, if possessed of the necessary qualifications, should be eligible to render such additional services; (c) that the clinical staff of any such additional service should be engaged on a part-time basis and should be remunerated on a time basis, and that a medical committee should play an important part in its selection.

(V.) That the Insurance Acts Committee be authorised on behalf of Local Medical and Panel Committees and in conjunction with other professional organisations to continue to hold "round table conferences" with the central Government department with regard to the extension of the service to the dependants of insured persons, the provision of residential institutional treatment, and the administrative arrangements which should be established for the proper provision and supervision of the service.

And these were confirmed by the vote of the Conference.

## THE OXFORD OPHTHALMOLOGICAL CONGRESS, 1919.

### ANNUAL MEETING.

THE tenth annual meeting of the Oxford Ophthalmological Congress was held on July 10th and 11th last in beautiful weather. Members were lodged in Keble College and the scientific proceedings took place in the Department of Human Anatomy of the University (kindly lent for the purpose by Professor Arthur Thomson), where technical and commercial museums were also arranged.

The programme was opened on July 10th by an address of welcome by the Master, Mr. SYDNEY STEPHENSON.—Major WALTER H. KIEP, R.A.M.C., read a paper on the Ocular Complications of Dysentery, which was followed by a good discussion on the subject.—Major EDGAR H. SMITH, R.A.M.C., read a communication dealing with "Quinine Amaurosis," well discussed by the members present.—Dr. WILLIAM MCLEAN, of New York, described his further experimental studies in intra-ocular pressure and tonometry, and exhibited his latest model tonometer.

A discussion on

#### *Preventive Ophthalmology*

was introduced by Colonel J. HERBERT PARSONS, C.B.E., consulting ophthalmic surgeon to the Forces. Colonel Parsons pointed out that the scope of his subject dealt with the prevention of damage (a) to the individual, and (b) to others. (a) Included many subjects, such as prevention of damage to the eyes from accidents, defective illumination, deleterious rays and organisms, and the prevention of damage to health from headache, accident, fatigue, &c.; (b) included regulations for the prevention of the transference of contagious disease and rules for Navy, Army, Air Force, Mercantile Marine, railways, motor industry, cinemas, and so forth. The problems of preventive ophthalmology constituted a question of collective action, and were of particular value at the moment, when projects of reconstruction were to the fore. In connexion with the prevention of accidents to the eyes in factories, there is urgent need of a scale of awards for compensation founded upon scientific principles. The formulation of regulations for the public services demanded (1) a widening of the basis of education of ophthalmologists; (2) coöperation between ophthalmologists and other experts; and (3) improvement in the methods of examination of candidates and the selection of examiners.

After the discussion the Doyné Memorial medal was presented to Colonel Parsons by the Deputy Master, Mr. PHILIP H. ADAMS. In the afternoon members and their friends were entertained to tea in the gardens of Trinity College by Mr. D. N. Nagel, M.A., and Miss Nagel. In the evening the annual dinner of the Congress was held in the hall of Keble College, some 70 members and visitors being present. The toast-list was commendably brief.

After dinner the annual general meeting of the Congress was held in the junior common room at Keble College. Among other things it was determined, on the motion of Mr. J. B. STORY, to make representations to the General Medical Council in support of those recently preferred to that body by the Council of British Ophthalmologists concerning the instruction and examination of medical students in eye work. Readers of THE LANCET are aware that the recommendations in question have been rejected by the General Medical Council.

On July 11th the proceedings began with a paper by Dr. S. LEWIS ZIEGLER, of Philadelphia, on the Problem of the Artificial Pupil; Knife-Needle *versus* Scissors.—Dr. P. BAILLART, of Paris, followed with a communication dealing

with his dynamometer for determining the blood pressure in the branches of the central retinal artery.—Mr. A. F. MACCALLAN (Cairo) read a paper on the Seasonal Variations of Acute Conjunctivitis in Egypt.—Colonel A. H. TURBY entered a suggestive plea for investigation as to any possible connexion between skeletal asymmetry, on the one hand, and defects of the eye, on the other.

A discussion upon Employment for the Blind was introduced by three blind speakers—namely, Mrs. ADOLPHUS DUNCOMBE, Captain PEIRSON WEBBER, and Captain TOWSE, V.C., and it is to be hoped that useful action will be undertaken by the Congress in connexion therewith.

In the afternoon the Ashhurst War Hospital at Littlemore, near Oxford, was thrown open to members by Lieutenant-Colonel T. S. GOOD, R.A.M.C.

The Congress was well attended, and a pleasing feature was the presence of representatives from Canada, Australia, Egypt, the United States, France, and Norway.

## TUBERCULOSIS.

### *The Establishment and Conduct of a Tuberculosis Sanatorium.*

THE Department of Health of the city of New York has published a monograph of 138 pages on the above subject by Dr. Charles B. Slade, visiting physician to the Municipal Sanatorium at Otisville. This book is full of good and much-varied advice, and deals with as widely different subjects as climate, building plans, and the qualifications to be found in the ideal sanatorium physician. Even the attitude of residents to a sanatorium in their neighbourhood is discussed. The author calculates that sanatorium accommodation should be provided for not less than 1 to 3 per 1000 of the community for which it is established. A complete sanatorium, with a capacity for 500 or more patients, should consist of five units—a reception, a men's, a women's, a children's, and an administration unit. A medical superintendent should be "of good moral character and temperate habits," and he should have practised his profession with reasonable success for several years, have had one to three years' "internship" in a general hospital, several years' experience in outdoor clinics for tuberculosis, some familiarity with the conduct of sanatoriums, and a wide knowledge of people. The monograph also discusses such vexed questions as the remuneration of work done by patients and ex-patients. The physical examination of the chest, the daily routine of a sanatorium, principles of treatment, after-care, and a host of other subjects come under review.

### *Annual Report of the Tuberculosis Officer for Wigan.*

This report, which is for 1918, in addition to giving the usual statistics, records the fact that the cases received direct from the Army, through the Insurance Commissioners, were in a comparatively early stage of the disease, and the prospect of restoration to working capacity was correspondingly good. But 48.8 per cent. of the 217 deaths between July, 1912, and Dec. 31st, 1918, occurred within six months of application for sanatorium benefit. This deplorably high percentage is regarded as absolute proof of the urgency of the need for still further coöperation between the panel doctors and the tuberculosis dispensaries.

### *Trudeau Sanatorium: Thirty-fourth Annual Report.*

Of the 259 patients discharged in the year under review, 52.9 per cent. were classified as cases of arrest or quiescence. In a further 13.1 per cent. the disease was improved, and in 17.7 per cent. the patients were either not tuberculous or classified merely as tuberculosis suspects. A notable fact was the increasing number of patients in whom the diagnosis of tuberculosis was in doubt (42), and this was interpreted as the result of the widespread educational campaign that had taught patients to seek advice early, and physicians to send more persons with suspicious symptoms for observation. The staff has found the study of these cases most instructive and excellent material for demonstration to the Trudeau School. The good results achieved by the radical bed-rest method have been maintained, but graduated exercise was the treatment adopted for the majority. Tuberculin was largely discontinued and artificial or natural light treatment was adopted in a few cases. The

influenza vaccine, which was given to a large number of patients, seemed to be harmless as well as prophylactic. No fewer than 125 former patients and members of the staff joined the various services; with what result is not stated. The work of the X ray laboratory included 2000 examinations, requiring 5000 plates, and 1500 fluoroscopic examinations. The principal occupations for the patients were basket-making, clay-modelling, photography, and typewriting. At the fourth session of the Trudeau School of Tuberculosis, 25 physicians and medical students were enrolled; of the 59 physicians trained during the four sessions, most have taken a definite position in tuberculosis work.

### *Injections of Saccharose in Pulmonary Tuberculosis.*

Writing in the *Corresp. Bl. f. Schweiz. Arzt.* for April 12th Dr. P. von Schulthess-Rechberg notes that, in his experience, the beneficial action of saccharose in pulmonary tuberculosis appears to be limited to a reduction of the sputum. Of the nine patients thus treated six reacted with severe local as well as with general disturbances, and also with a rise of temperature. One patient died a fortnight after the treatment was started, and four gave it up on account of the reactions provoked. In four cases the reduction in the amount of sputum varied between 20 and 80 per cent. In all but one case there was no corresponding improvement in the physical signs. The most important observation in this series of cases is that the injections, whatever their merits, are liable to provoke serious and even dangerous reactions.

## MEDICINE AND THE LAW.

### *Professional Secrecy: The Military Aspect.*

THE question of professional secrecy, difficult enough in England, is in France posed on a somewhat different basis. At a meeting of the Société de Médecine Légale (de Paris), according to the *Presse Médicale* (1919, xxxvii., 367), M. Granjux discussed some military aspects of the problem, for apparently there have been medical "incidents" and, it is suggested, administrative "errors" that have provoked public comment. At any rate, M. Granjux feels that two separate sets of circumstances should be distinguished. In the first, a soldier (officer or man) reports, or "goes sick," as we say, and is seen by the medical officer in the course of familiar routine. The ordinary social and ethical relationship and obligations, as between doctor and patient, do not then obtain; military administration and disciplinary necessities alone are involved, and the civil issue of professional secrecy cannot arise. In the second case recognised by M. Granjux, the circumstances, though not unknown, are less familiar to those who have served in the R.A.M.C. We are here asked to consider the case of a "militaire" (officer or man) who seeks the advice or services of the doctor without first going through the process of "reporting sick." Then, says M. Granjux, the surgeon must respect his patient's confidence. It appears, however, that when a "militaire" who has thus sought and obtained the advice of his battalion medical officer is afterwards compelled to "go sick," the ethical rule recognised by all officers of the Corps de Santé is to forget all that has passed, and to begin again on a purely military and official footing.

### *The Civil Aspect.*

At the same session as that at which the military difficulty was discussed, M. Berthélemy reopened the civil question, which has become recently, in France, of some moment. While, on the one hand, the proposal to make obligatory the notification of tuberculosis has provoked many objections; on the other, the crusade against criminal abortion bids fair to involve doctors in many difficulties. As is well known, the French Penal Code, by Article 378, constitutes the violation of professional secrecy a punishable offence, save only when the breach is in response to the definitely imposed legal obligation to give information under certain circumstances. As the result of certain decisions of the Cour de Cassation, however, the law, in the words of M. Berthélemy, has converted the custom of professional secrecy into a tyrannical obligation laid upon medical men, overriding the social duty of assisting justice. And M. Berthélemy thinks that it has been an error thus to convert what should be a facultative means of escape from

the witness-box into an absolute prohibition of the right to perform a duty to society.

We gather that it is now proposed, in certain legal instruments designed to check the practice of criminal abortion, to enforce the rigid application of the doctrine of professional secrecy by the clearest legal provision—the impulse coming from the public rather than from the profession. M. Berthélemy thinks, however, that it were better for medical men to be absolved from the social duty in particular circumstances rather than to be forbidden ever to perform it.

#### *An International Contrast*

This striking contrast then obtains: that while in England the effect of the strict interpretation of the law is to impose on medical men the "social duty" of giving information of the commission of a crime, and is in opposition to the views of that body of professional opinion (recently voiced by Sir John Tweedy) which clings to the sanctity of the professional secret as a professional privilege; in France, on the other hand, there is an apparently strong current of professional resentment against the proscription by the law of the right to exercise, save under extremely limited conditions, the duty to society. It is not suggested for one moment that our French brethren are less scrupulous than are we in their allegiance to the spirit and letter of the Hippocratic oath, but they are clear-headed and logical enough to recognise the possible evil to the State if medical men, in response to public clamour, are forced to "contract out" of social obligations which are not less incumbent on them than on others.

## AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

#### *The Influenza Epidemic.*

THE progress of epidemic influenza has shown little that is new during the past month. In Sydney there has been a gradual decline, and early in May the Government removed all restrictions, including the wearing of masks in trains and trams. There are no figures which are at all accurate as to the extent of the outbreak, but the number of deaths will be not short of 1000 in New South Wales for the present wave. In Melbourne the attack-rate, as gauged from the death-rate, has been curiously steady, and from 20 to 30 deaths are being still reported daily for the whole of Victoria. The disease has been just as prevalent in country districts as in towns, and severe cases are as often met with. Brisbane is now definitely suffering from an epidemic, but as yet the dimensions are not alarming. Adelaide has also now become infected, although the number of cases is not great. Several well-known medical men have succumbed to the disease in different States, and scarcely any practitioner has escaped more or less severe infection. The resident medical officers at all hospitals have been at some time patients during the past few months.

There is as yet no clear-cut evidence as to the value of any preventive measure adopted during the epidemic, but opinion is crystallising that nothing so far attempted has been of any avail in staying the spread of influenza. The experience of public mask-wearing in Sydney does not support the idea that it is worth while, and it has been regarded by all as very irksome and disagreeable. Inhalatoriums in which medicated steam was supplied for a few minutes were loudly advocated by some, but in Sydney the medical committee, after employing them, condemned them as harmful. In Melbourne they were never used except by the Public Health Department at a hospital and at the quarantine grounds. Inoculation may be said to have lost most of its friends and supporters, both lay and professional. Some observers still persist that it modifies the symptoms, but this is purely a personal opinion, and no evidence in support of the assertion is produced.

In Victoria the acting Minister of Health has appointed Dr. H. Newton as controller of influenza hospitals, and has also created an additional staff of transport and organisation in connexion with the epidemic aspect of influenza. This work was in the hands of the chairman of the Board of Public Health, but it has proved too much for a single direction, and the change was made in response to public clamour for more vigorous action. No considerable steps have as yet resulted from the new policy.

#### *Melbourne University: an Overcrowded Medical School.*

The Council of the Melbourne University approached the Victorian Government with a request for money in order to provide increased accommodation for students. Every school is said to be overcrowded, but the urgent requirement is in the medical school, which during the past two years has been taxed to breaking point to find room for first- and second-year students. It was proposed some time ago to remove the medical school to a separate site in the vicinity of the hospitals, but this scheme failed to attract political support, although it was approved by the profession and by some of the University staff. The Premier was sympathetic to the recent deputation and has undertaken to find a sum of £200,000 to build and equip new class-rooms and laboratories.

#### *Veneral Disease.*

A return has been issued of the number of cases of venereal diseases notified in Victoria for the year 1918. It appears that 6790 persons were affected (State population about 1,250,000). Gonorrhœa was returned alone in 4878 cases, syphilis in 1686, and the two in combination in 99 patients. The remainder were various combinations of infection. In Victoria the diseases are compulsorily notifiable and there are penalties for neglecting treatment. There are clinics for treatment managed wholly by the Government, and some of the general hospitals have been brought into the scheme although the provision on this regard is not yet very great.

#### *Personal.*

Colonel H. Maudsley, C.M.G., C.B.E., has arrived in Melbourne after an absence of four years on duty with the A.A.M.C. in Egypt and England. Colonel Maudsley is lecturer on medicine in the University of Melbourne and will take up his position shortly.

Lieutenant-Colonel Sir James Barrett, K.B.E., has also returned to Melbourne and resumed private practice.

The death is announced of Surgeon-General Sir W. T. Williams, who was the Director-General of the Commonwealth Military Forces at the outbreak of war, but resigned owing to ill-health. General Williams had a distinguished record in the Boer war with the New South Wales contingents, and was the first Director-General of the Federal military organisation.

May 27th.

## URBAN VITAL STATISTICS.

#### VITAL STATISTICS OF LONDON DURING JUNE, 1919.

IN the accompanying table will be found summarised statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the ten diseases notified in the table was equal to an annual rate of 4·7 per 1000 of the population, estimated at 4,026,901 persons; in the three preceding months the rates had been 4·5, 4·6, and 4·5 per 1000. Among the metropolitan boroughs the lowest rates from these notified diseases were recorded in Hammersmith, the City of Westminster, Hampstead, St. Pancras, the City of London, and Wandsworth; and the highest in Chelsea, Holborn, Bethnal Green, Stepney, and Southwark. Two cases of small-pox were notified during the month, against 7, 2, and 3 in the three preceding months; these cases belonged respectively to Stepney and Lambeth. The cases of small-pox under treatment in the Metropolitan Asylums Hospitals at the end of the month numbered 2, against 6, 1, and 3 at the end of the three preceding months. The prevalence of scarlet fever was slightly more than in the preceding month; this disease was proportionally most prevalent in Finsbury, Stepney, Southwark, Lambeth, Deptford, and Greenwich. The Metropolitan Asylums Hospitals contained 1132 scarlet fever patients at the end of the month, against 1009, 1043, and 1066 at the end of the three preceding months; the weekly admissions averaged 157, against 126, 138, and 150 in the three preceding months. The number of notified cases of diphtheria was the same as in the preceding month; the greatest prevalence of this disease was recorded in Kensington, Chelsea, Holborn, Shoreditch, Bethnal Green, and Southwark. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1152, 1134, and 1086 at the end of the three preceding months, numbered 1021 at the end of June; the weekly admissions averaged 138, against 164, 151, and 145 in the three preceding months. Twenty-four cases of enteric were notified during June, against 13, 18, and 22 in the three preceding months; of these cases, 5 belonged to Kensington, 3 to Poplar, 2 to Paddington, and 2 to Lewisham. There were 25 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 16, 16, and 19 at the end of the three preceding months; the weekly admissions averaged 5, against 3, 2, and 3 in the three preceding months. Erysipelas was proportionally most prevalent in Stoke Newington, Holborn, Bethnal Green, Poplar, and Southwark. The 18 cases of puerperal fever notified during the month included 2 each in Islington, Poplar, Wandsworth, Camberwell, and Deptford. Of the 14 cases of cerebro-spinal meningitis 2 belonged to Battersea and 2 to Greenwich; while of the 6 cases of poliomyelitis 2 belonged to St. Marylebone.

## ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JUNE, 1919.

(Specially compiled for THE LANCET.)

CITIES AND BOROUGHES.	Estimated civil population, 1917.	Notified Cases of Infectious Disease.											Deaths from Principal Infectious Diseases.											
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other con- tinued fevers.	Puerperal fever.	Erysipelas.	Cerebro-spinal meningitis.	Poliomyelitis.	Total.	Annual rate per 1000 persons living.	Small-pox.	Measles.	Scarlet fever.	Diphtheria.*	Whooping- cough.	Enteric fever.	Diarrhoea and enteritis (under 2 years).	Total.	Annual rate per 1000 persons living.	Deaths from all causes.	Death rate per 1000 living.

\* Including membranous croup.

The mortality statistics in the table relate to the deaths of civilians belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased had previously resided. During the four weeks ended June 28th the deaths of 3011 London residents were registered, equal to an annual rate of 9.7 per 1000; in the three preceding months the rates had been 20.9, 15.0, and 11.1 per 1000. The death-rates ranged from 7.3 in the City of London, 7.6 in Deptford, 8.2 in Hammersmith, 8.4 in Hampstead, and 8.5 in Fulham, to 10.7 in Bethnal Green, 10.9 in Lambeth, 11.0 in Stoke Newington, 12.0 in Kensington, 12.1 in Shoreditch, and 12.5 in Finsbury. The 3011 deaths from all causes included 107 which were referred to the principal infectious diseases; of these, 23 resulted from measles, 6 from scarlet fever, 37 from diphtheria, 6 from whooping-cough, and 35 from diarrhoea and enteritis among children under 2 years of age. No death from any of these diseases was recorded in Holborn, Finsbury, the City of London, and Shoreditch. Among the metropolitan boroughs the lowest death-rates from these diseases were recorded in the City of Westminster, Bermondsey, Battersea, Wandsworth, and Deptford; and the highest in Kensington, Hammersmith, St. Marylebone, Bethnal Green, and Southwark. The 23 deaths from measles were less than a fifth of the average number in the corresponding period of the five preceding years; of these deaths 4 belonged to Kensington, 3 to St. Pancras, 3 to Bethnal Green, and 2 to Lambeth. The 6 fatal cases of scarlet fever were 7 below the average number. The 37 deaths from diphtheria were one less than the average; of these deaths 7 belonged to Southwark, 5 to Hackney, 5 to Lambeth, 3 to Islington, and 3 to Woolwich. The 6 fatal cases of whooping-cough were one-twelfth of the average number; of these, 2 belonged to Camberwell. No death from enteric fever was recorded during the month, against an average of 9. The 35 deaths from diarrhoea and enteritis among children under 2 years of age were 20 less than the average number; of these deaths, 5 belonged to Camberwell, 4 to Lambeth, 3 to Hammersmith, 3 to Islington, and 3 to Stepney. In conclusion, it may be stated that the aggregate mortality from these principal infectious diseases in London during June was 66 per cent. below the average.

(Week ended July 19th, 1919.)

*English and Welsh Towns.*—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had been 9.6, 10.0, and 10.1 in the three preceding weeks, declined to 9.0 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the annual rate was 9.2, or 0.8 per 1000 below that recorded in the previous week, while among the remaining towns the rates ranged from 3.3 in Norwich, 4.4 in Wakefield, and 4.5 in Coventry, to 13.8 in Stoke-on-Trent, 14.2 in Gillingham, and 14.7 in Darlington and in Sunderland. The principal epidemic diseases caused 109 deaths, which corresponded to an annual rate of 0.3 per 1000, and included 35 from diphtheria, 34 from infantile diarrhoea, 19 from measles, 11 from whooping-cough, 6 from scarlet fever, and 4 from enteric fever. The mortality from these diseases showed no marked excess in any town. There were 5 cases

of small-pox, 1438 of scarlet fever, and 1100 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 6, 1348, and 1068 respectively at the end of the previous week. The causes of 21 deaths in the 96 towns were uncertified, of which 4 were registered in Birmingham, and 2 each in London, Stoke-on-Trent, Middlesbrough, Darlington, and Gateshead.

*Scotch Towns.*—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality, which had been 11.5, 9.9, and 11.0 in the three preceding weeks, fell to 10.6 per 1000. The 227 deaths in Glasgow corresponded to an annual rate of 10.6 per 1000, and included 10 from whooping-cough, 4 from diphtheria, and 3 each from measles and infantile diarrhoea. The 59 deaths in Edinburgh were equal to a rate of 9.1 per 1000, and included 1 each from measles, whooping-cough, and infantile diarrhoea.

*Irish Towns.*—The 70 deaths in Dublin corresponded to an annual rate of 9.0, or 4.1 per 1000 below that recorded in the previous week, and included 6 from infantile diarrhoea. The 84 deaths in Belfast were equal to a rate of 10.9 per 1000, and included 1 each from measles, scarlet fever, diphtheria, and infantile diarrhoea.

**BRISTOL HOSPITAL SUNDAY FUND.**—Mr. J. H. Reed has retired from the honorary secretaryship of this fund after 21 years, during which time nearly £47,000 have been collected for the Bristol medical charities, and the annual total of a few hundreds increased to £5300.

**DONATIONS AND BEQUESTS.**—By the will of the late Mr. W. Shepherd, of Clapham Park and Guildin-hurst Manor, Sussex, who left property of the value of £600,000, the testator has bequeathed the larger part of this sum to London hospitals.—Under the will of the late Mr. Longueville Gladstone, of Liverpool, the testator has left £1000 to the Liverpool Royal Infirmary, £700 to the Royal Southern Hospital, £500 each to the David Lewis Northern Hospital, Stanley Hospital, and the School for the Indigent Blind, and £2000 for such other charities as the executors and Mayor of Liverpool may select.—The late Miss Mary Austin, of Bath, has, among other bequests, left £500 each to the Finsbury Dispensary, Clerkenwell, and to the Norwood Cottage Hospital, and, on the death of her sister, £500 each to the Middlesex Hospital, Westminster Hospital, Guy's Hospital, and the Royal United Bath Hospital.—Subject to the life-interest of two sisters, the late Dr. J. Duff, of Chester, has left by will property of the value of £9752 to Glasgow University to form a Fellowship for the elucidation of malignant diseases.

## INCIPIENT MENTAL DISEASES.

To the Editor of THE LANCET.

SIR,—In reports of committees, in articles in medical papers, in books recently published, and in last year's report of the Board of Control the early treatment of these cases without certification and by simple notification has been earnestly suggested. Now a whisper reaches me that during the next session the Ministry of Health intend to bring in a short Bill dealing with these cases, and my very heart rejoices.

One great drawback to the early treatment of mental diseases has not only been the Lunacy Act of 1890, but also the curious unreasonable attitude of the general public, who still insist in looking at mental disease as a "stigma" on the family. By allowing these cases to be under the Board of Control, which deals only with mental diseases, and under their supervision, as suggested in their last year's report, this "stigma" would still exist; whereas if these cases are dealt with by the Ministry of Health, together with all sorts of other diseases, the idea of "stigma" will be done away with.

There are, however, some important points to be considered and brought to the notice of the general public.

(1) There seems to be difficulty in the minds of those who are bringing in this Bill as to the way in which these cases should be defined. Should they be called: (a) not certified cases, (b) uncertifiable cases. Personally I prefer the latter definition, as the first one leaves the question open as to whether or no they are certifiable.

(2) *Supervision.*—These cases must be under some supervision. I feel sure the Ministry of Health will deal with these cases with regard to proper supervision in the most humanitarian manner. The Board of Control, in their 1918 report, agree as to the necessity of supervision, but do not see their way to carry it out with their present staff and the work they have already in hand, so it ought to be a comfort to them to find the Ministry of Health are taking up this matter.

(3) As to who should take charge of these cases it seems to be obvious that the more skilled supervision and treatment they come under the greater will be their chance of recovery. Single cases may be in some instances easily and properly placed, but I am strongly of opinion that "approved homes" for such cases should be permitted, as are now allowed for cases of mental deficiency. Such approved homes should be under the charge of experienced physicians if good results are to be obtained.

(4) Limitation of sojourn for such cases. It has been suggested, both by the Board of Control and committees, that such period should be for six months only. To my thinking this is utterly wrong, unless such period be renewable in certain cases. A patient may be nearly well when the six months has expired. To suddenly take such a patient from the care and treatment and the environment in which he or she has got well to some new home surroundings and treatment might be fatal. I therefore consider that the six months should be renewable in certain cases.

We who have spent our lives in treating mental diseases in all stages have only one wish, and that is to increase the recovery rate of mental diseases, which has stood still during the last 60 years. I trust my suggestions will meet not only with your approval, but with that of the medical profession, the general public, and the Ministry of Health.

I am, Sir, yours faithfully,

July 21st, 1919.

LIONEL A. WEATHERLY, M.D.

## PARAFFIN WAX IN FACIAL SURGERY.

To the Editor of THE LANCET.

SIR,—In your issue of July 19th Lieutenant-Colonel Spencer Mort contributes a very interesting and carefully thought-out article on this subject, and advises the use of paraffin wax for facial scars and depressions of contour of the face. There is no doubt that his method of insertion of paraffin wax is the most practical and fruitful in giving good

immediate results. I cannot, however, let the opportunity pass without entering a protest against the practice of insertions into the facial tissues of any foreign body, and of wax in particular. Before my department was moved en bloc to Sidcup it had been clearly shown by myself and my colleagues that the natural tissues of the body, in the form of autologous grafts or tissue flaps, give ultimate results quite as cosmetic as those of any foreign body implantation.

In regard to paraffin, in 1916 I was inserting it in blocks, and I also used the syringe method, which gives such excellent immediate results with those who are familiar with the method, particularly the Bond Street beauty specialists. I thoroughly agree with Colonel Mort in condemning this practice; in fact, I should go so far as to say that the injection of melted paraffin into the face is a practice that should be prohibited by law. A solid block of paraffin wax is better than the injected wax, in that the late bad results are fewer and more easily dealt with; at the same time, fibrosis must naturally occur round any block of paraffin in the attempt, sometimes successful, of the tissues to get rid of the foreign body. When placed deep I admit little harm comes therefrom, but I think the practice is a retrograde step.

The class of case with which Colonel Mort states he has had the best results—viz., depressed scars—can easily be remedied by excision of the scar tissue and the use of subcutaneous flaps to build up the contour. In the larger depressions cartilage implantations or muscle flaps, combined with complete and total excision of the scar, give the most perfect results possible. This opinion is shared by all my facial colleagues at the Queen's Hospital, and, in particular, by our consulting surgeon, Sir William Arbuthnot Lane.

I am, Sir, yours faithfully,

H. D. GILLIES, F.R.C.S.,

London, July 23rd, 1919.

Major, R.A.M.C.

## NATIONAL HEALTH INSURANCE AND THE MEDICAL GUILD.

To the Editor of THE LANCET.

SIR,—I have been instructed by Dr. John Playfair, the President, and the Executive Committee of the Medical Guild to submit for your consideration the following suggestions embodied in certain resolutions passed at recent meetings of the Guild, after full consideration of the Memorandum of the Insurance Commissioners and the report of the Insurance Acts Committee of the British Medical Association on the Revision of the Conditions of Service under the National Health Insurance Acts and possible extensions of service:—

(1) That professional attendance and treatment given to any insured person by any registered medical practitioner acting solely on the usual understanding subsisting between a practitioner and his private patient shall be recognised as medical benefit for that person, and such person shall receive a just contribution from moneys provided for medical benefit towards the payment of such attendance and treatment.

(2) That obstetric practice should not be included within the range of National Health Insurance.

(3) That tuberculosis should be excluded from the range of National Health Insurance.

(4) That the National Health Insurance Acts as at present administered should not be extended, with the exception of specialists' advice to the present insured.

(5) That a State Medical Service is of urgent necessity for the genuinely necessitous classes of the community and for them only.

With regard to the first of these resolutions or suggestions, it has been estimated that there are approximately 20,000 insured persons in Edinburgh who receive professional attendance and treatment from non-panel practitioners, and as this number is increasing annually it is a matter of justice that those persons should be allowed a money contribution towards payment of such attendance and treatment, especially when the fact is taken into account that the large sum of money for payment of the medical benefit of those persons is being paid to, or distributed among, the panel practitioners who do not work and never will have the opportunity of working for this money. This statement is applicable to other towns and cities.

I am, Sir, yours faithfully,

FREDERICK PORTER,

Edinburgh, July 15th, 1919.

Honorary Secretary.

## THE ORIGIN OF LIFE: THE WORK OF THE LATE CHARLTON BASTIAN.

*To the Editor of THE LANCET.*

SIR,—Dr. Albert Mary's letter in *THE LANCET* of June 28th is most interesting, and his experiments show that Dr. Bastian's results are probably due to chemical actions of a catalytic nature; but the influence of osmotic pressure, by diffusion effects in colloid solutions, is also an important factor that must not be neglected in such operations. Dr. Stéphane Leduc has obtained some very remarkable results in this connexion.<sup>1</sup> Artificial bodies, known since Butschli's day as *simulacra*, can be brought about apparently without the aid of life.<sup>2</sup> In many chemical reactions, as well as purely physical ones, there is a swift passage of electrons, both positive and negative, through the medium in which the reaction takes place. I may perhaps mention in this connexion the very beautiful experiments by Emil Hatschek,<sup>3</sup> which show on a larger scale that the swift passage of a body, or even a drop of liquid, through a "gel" can give rise to motions of the nature of vortices in the "gel," resembling organisms; and I conceive that many chemical reactions and the emission of  $\alpha$  and  $\beta$  particles from radioactive substances, immersed in colloid mediums, should do so likewise, producing such vortex motions resembling bacteria on a much smaller scale. In fact, I have described phenomena of this kind in *Nature* (May 25th, 1905), and in the *Fortnightly Review* (September, 1905), as well as in my book "The Origin of Life," 1906. These bodies, which I called at the time *radiobes* owing to their mongrel origin, differ considerably from the precipitated products of barium, strontium, or lead, as might have been expected. But this is a point that some observers seem to have overlooked, for the products of radium are something more than mere precipitates as their behaviour shows, and have many of the properties of living organisms, though not all of them, since they do not produce subcultures, perhaps owing to the medium being unsuitable, as in Dr. Mary's experiments. It seems to me, then, that both Dr. Bastian and Dr. Mary's results may be explained by the setting up of such vortex motions through catalysis and the rapid interchange of electrons which it involves, whilst in some cases by mere diffusion and osmosis, as in the experiments of M. Leduc already referred to. But, as I have found, the immersion of a radio-active substance in a colloid medium facilitates their production, and this, no doubt, for the dynamical reasons which I have just endeavoured to explain.

I am, Sir, yours faithfully,

Kingston Hill, July 17th, 1919.

J. BUTLER BURKE.

## QUININE AS A PROPHYLACTIC IN MALARIA.

*To the Editor of THE LANCET.*

SIR,—When serving at Sierra Leone about ten years ago I came across the following extract from the medical history of the war in the Gold Coast Protectorate in 1873, written by Deputy Surgeon-General Sir A. D. Home, V.C., K.C.B.:—

"The use of quinine as a prophylactic against 'fever' to the troops on the Gold Coast had been one of the sanitary instructions of the D.G. issued to the P.M.O. on his assuming charge.

It need not be said that the use of the drug in this way to men employed on duty on malarious coasts is an established practice in the Navy, one recommended by the authority of high professional opinion as to its value. Accordingly, Army medical officers serving on the Coast were requested in Departmental orders to give quinine daily in a prophylactic dose.

It was not possible to procure the information asked for as to the influence of quinine in warding off attacks of fever, as medical officers had been changed so frequently and the composition of the detachments had varied so much that continuous observation of the same individuals, even for one month, was unattainable.

On so important a subject, however, in the absence of precise data, it may be desirable to state the conclusions come to with respect to it from observation.

With regret, and heartily wishing that my opinion may be overthrown by others, I have to say that I did not recognise any value in quinine given prophylactically. It neither seemed to ward off attacks or to mitigate the severity of malarious fevers in those attacked. With the exception that in some men a daily 3 gr. dose produced transient deafness, and in a few others nausea, no untoward symptoms followed the use of the medicine. On the other hand, I was unable to agree with the startling opinion seriously propounded to me by some men of the West India Regiment encamped at Fort Napoleon, that the quinine given daily as a prophylactic had given them the ague from which they suffered."

During the year I acted as senior medical officer every soldier stationed at Freetown got 10 gr. on Thursday and

<sup>1</sup> See his "Mechanism of Life," translated by Dr. Deane Butcher, 1911.

<sup>2</sup> Microscopic Foam and Protoplasm, 1894.

<sup>3</sup> Proc. Roy. Soc., Series A, vol. xcv., No. 669.

15 gr. on Friday. I kept its administration in the hands of one officer whom I placed in charge of the Tower Hill Hospital, and in order that there should be no break I arranged to keep him there for the whole year.

He reported 25 per cent. less attacks than during the previous year!

I consider that if he had been able to report a diminution of, say, 75 per cent., one would have been justified in thinking that quinine in these doses had acted as a prophylactic. The number of cases might easily vary to the extent reported from other causes.

Curiously enough, a soldier of the West India Regiment told me that his bi-weekly dose of quinine was invariably followed by an attack of ague.

I am, Sirs, your faithfully,

F. J. W. PORTER,  
Major, R.A.M.C. (retd.).

Bombay, June 14th, 1919.

## PROFESSIONAL SECRECY IN THE EYE OF THE LAW.

*To the Editor of THE LANCET.*

SIR,—Sir John Tweedy's letter in your issue of July 5th, dealing with the accepted canons of the medical profession in disclosing the confidences of patients, suggests an analogy with confidences made to the clergy. Some of your clientele are old enough to recall the "Road" murder, which for a long time baffled detection. Then the Rev. A. D. Wagner, who was vicar of St. Paul's, Brighton, and who ran an Anglican Conventual establishment in that town, induced one of his penitents, who had confessed to him that she was guilty of the crime, to make a clean breast of it to the civil authorities. If I remember rightly, for it was in the early "sixties," the line that this clergyman took was that he himself was unable to divulge what had been told to him under confessional secrecy, but that he made it very patent to this poor unfortunate girl that if she was truly penitent she should make an open confession of the murder she had committed, which confession at the same time would exonerate such as were still under suspicion of having been the perpetrators.

Even now there is being discussed in the United States a very interesting example of a refusal to betray trust. Four years ago Judge Lindsey, of Denver Juvenile Court, had before him a certain boy with whom he had talked in his capacity as Juvenile Judge, and to whom he had given his solemn promise that he would not disclose any statement the boy made to him. Plainly the element of confidence between the judge and the child is essential to the success of the Juvenile Court. As plainly, to destroy this relationship would be, in effect, to nullify and set aside the chief end and purpose of the Juvenile Court.

I am, Sir, yours faithfully,

THEODORE P. BROCKLEHURST,

July 14th, 1919.

Rector of Giggleswick-in-Craven.

## PENTOSURIA.

*To the Editor of THE LANCET.*

SIR,—With reference to your annotation under the above heading in *THE LANCET* for July 19th (p. 117), my experience may be interesting as bearing on the frequency with which this condition is met with. During the month of June I saw 56 cases diagnosed as diabetes mellitus, and of these 11 proved to be passing pentoses in their urine; 9 were found to be of the alimentary type, the characteristic diphenylhydrazone and para-bromophenylosazone of l-arabinose being recovered from the urine; and 2 were cases of true, or essential, pentosuria, the first examples of this condition met with in England, I believe. One of these cases of essential pentosuria passed l-arabinose alone; the other excreted a mixture of this sugar with dextrose and pseudo-lævulose. Under treatment the dextrose and pseudo-lævulose soon disappeared from the urine of the latter, leaving the inactive pentose. These cases are being investigated further, but it is interesting to note that both of them had been treated for diabetes for some time before I saw them, one for 16 years and the other for one year. In 4 of the cases of alimentary pentosuria l-arabinose was the only sugar found in the urine, in 4 it was associated with more or less dextrose, and in 1 there was a small percentage of true lævulose. My observations suggest that alimentary

pentosuria is commonly associated with hepatic disturbances, and it is partly to this that the lowered tolerance for pentose is probably due. The amount of fruit taken by these patients was in no case large, and in all of them analysis of the urine revealed evidence of hepatic insufficiency. I am, Sir, yours faithfully,

P. J. CAMMIDGE.

Nottingham-place, Marylebone, W., July 13th, 1919.

## THE ABILITIES OF THE DISABLED.

To the Editor of THE LANCET.

SIR,—On Friday, July 25th, a meeting has been arranged in Central Hall, Westminster, at 3 P.M., specially designed to interest and encourage men who have suffered some physical disability during the war. The meeting is under the joint auspices of the British Red Cross and the London War Pensions Committee, and Sir Laming Worthington Evans will preside. Two of the speakers, both of whom have suffered the loss of more than one limb and have "made good" in the face of incredible handicaps, will give demonstrations of what is possible with the simplest of artificial appliances. Interesting cinematograph films will be shown, and all discharged, disabled, and demobilised men will be heartily welcome; admission is free.

I am, Sir, yours faithfully,

(Mrs.) ETHEL M. WOOD,

Secretary, London War Pensions Committee.

Bloomsbury-square, W.C., July 16th, 1919.

## SUPERANNUATION OF SCOTTISH POOR-LAW MEDICAL OFFICERS.

To the Editor of THE LANCET.

SIR,—A deputation will shortly wait on the Secretary for Scotland with the object of having the Scottish Poor-law medical officers placed on a similar footing as respects superannuation with their English and Irish brethren. The Poor-law medical officers of the Highlands and Islands who serve under the Highlands and Islands Medical Service Board stand on a different footing from other Scottish Poor-law medical officers, their returns from private practice being very small and their income being mainly derived from Government sources. It is therefore desirable for this group of Poor-law medical officers to come under a separate scheme of superannuation, similar to that which at present obtains in the case of medical officers serving in the Navy and regular Army. I am, Sir, yours faithfully.

July 16th, 1919.

VOX.

## ENCEPHALITIS LETHARGICA.

To the Editor of THE LANCET.

SIR,—In the course of your article on this subject in THE LANCET of July 19th (p. 118) the following sentences occur:—

"Many observers are of the opinion that it is a disease allied to poliomyelitis; while others, mainly those who have made a special study of the history of the disease, incline to the view that encephalitis lethargica is associated in some intimate causal manner with influenza.<sup>6</sup> The latter point out that previous recorded epidemics of lethargy have been associated in point of time with epidemics of influenza, and they suggest that an attack of influenza either predisposes the patient to the lethargy or in some unexplained way activates the virus of lethargic encephalitis."

As the number (6) bears reference to an historical paper by myself, I have ventured to italicise several words, and will be obliged if you allow me the opportunity of saying (a) that I can myself form no idea of what is meant by the "view" that encephalitis lethargica is associated in some "intimate causal manner" with influenza; and (b) that I would be the last to claim credit for the amusing "predisposition" and "activation" hypotheses that someone has put forward in explanation of what is indisputable.

My belief is, simply, that no one who has studied the historical evidence can deny the "clinical affinities and epidemiological liaison between what we now call forms of epidemic encephalo-mylitis and meningitis ..... and the epidemic catarrhal fever, or influenza."

It is, moreover, just those who have studied the historical as well as the clinical and pathological evidence who support

the view that you have allowed me to put forward in your columns (May, 1918)—namely, that the epidemic of "encephalitis lethargica" last year was really a manifestation of Heine-Medin disease, or (to use the term which seems to give least offence) of epidemic encephalo-mylitis and meningitis, of which "acute anterior poliomyelitis" represents but a particular phase.

This view, as it appears from the special report of the Local Government Board on "encephalitis lethargica" (pp. 2 and 63), is substantially that held by Sir William Osler, and Dr. Draper of the U.S. Army—a fact which, rather singularly, has hitherto escaped comment.

I am, Sir, yours faithfully,

Wimpole-street, W., July 19th, 1919.

F. G. CROOKSHANK.

## The Services.

### MENTIONED IN DESPATCHES.

The names of the following are amongst those mentioned for distinguished and gallant services in a very lengthy despatch received from the Commander-in-Chief of the British Forces in France, covering the period from Sept. 16th, 1918, to March 15th, 1919:—

*Army Medical Service.*—Col. J. D. Alexander, D.S.O.; Capt. (acting Maj.) T. H. Boulton, M.C.; Col. F. W. Begbie; Lt.-Col. (temp. Col.) W. Bennett, D.S.O.; Temp. Capt. (acting Major) W. S. Berry; Col. W. W. O. Beveridge, C.B., D.S.O.; Col. R. J. Backham, C.M.G., C.I.B.; D.S.O.; Lt.-Col. (acting Col.) W. R. Blackwell, C.M.G.; Capt. (acting Maj.) H. E. A. Boldero; Capt. and Bt. Maj. (acting Maj.) L. G. Bourdillon, D.S.O., M.C.; Lt. Col. (temp. Col.) A. W. N. Bowen, D.S.O.; Lt.-Col. and Bt. Col. F. J. Brakenridge, C.M.G.; Col. H. A. Bray, C.M.G.; Temp. Capt. (acting Maj.) L. R. Broster; Maj. and Bt. Lt.-Col. C. G. Browne, D.S.O.; Lt.-Col. (temp. Col.) B. B. Burke, D.S.O.; Maj. Gen. (temp. Lt.-Gen.) C. H. Burtchall, K.C.B., C.M.G., K.H.S.; Lt.-Col. (temp. Col.) J. H. Campbell, D.S.O.; Maj.-Gen. H. arr, C.B.; Col. J. Clay; Lt.-Col. (acting Col.) H. Collinson, C.M.G., D.S.O.; Maj. D. M. Corbett; Capt. (acting Maj.) W. V. Corbett; Capt. (acting Maj.) J. Dale; Lt.-Col. B. R. Dennis, O.B.E.; Lt.-Col. (acting Col.) T. F. Dewar, C.B., T.D.; Capt. (acting Maj.) R. F. O. T. Dickinson; Lt. Col. and Bt. Col. (temp. Col.) H. E. M. Douglas, V.C., C.M.G., D.S.O.; Capt. (acting Maj.) C. R. Dudgeon, M.C.; Col. H. N. Dunn, C.M.G., D.S.O.; Maj. J. S. Dunne, D.S.O.; Lt.-Col. (temp. Col.) O. W. A. Elsner, D.S.O.; Lt.-Col. (temp. Col.) H. B. Fawcett, C.M.G., D.S.O.; Capt. (acting Major) A. McL. Ferrie, M.C.; Col. R. H. Fifth, C.B.; Lt.-Col. (acting Col.) Fitzg. G. Fitzgerald, D.S.O.; Lt.-Col. (temp. Col.) T. Fraser, D.S.O.; Capt. Messrs. H. K. Lewis and Co., Ltd., have removed their publishing, wholesale, and advertisement departments to 28, Gower-place, W.C.1. The change should provide more convenient accommodation for publishing work, while the space vacated in the old premises will afford additional room for the library, to which a new reading room will be added.

# Parliamentary Intelligence.

## HOUSE OF COMMONS.

TUESDAY, JULY 15TH.

### Public Health Propaganda.

To a written question if he would appoint a publicity committee to consider how best by posters, leaflets, lectures, and other means to educate the nation in the principles of health, Major ASTOR (Parliamentary Secretary to the Ministry of Health) replied: The Minister of Health has recently appointed a Committee to advise him on the dissemination of information in regard to housing, whether by the means indicated in the question or otherwise. I will send the honourable Member the names of the Members and the terms of reference to the Committee. My right honourable friend proposes to await their advice before proceeding to consider the question of publicity in relation to other problems affecting health.

WEDNESDAY, JULY 16TH.

### Dental Reform.

Mr. JESSON asked the Minister of Health whether an amending Bill to the Dentists Act, 1878, was in course of preparation; if so, whether this Bill would appoint, in accordance with the recommendations of the Departmental Committee of Dentistry, an ad hoc Committee to inquire into the eligibility of unregistered dentists for registration; whether the personnel of this ad hoc Committee had already been decided upon; whether the Incorporated Dental Society, Ltd., would have representatives upon it, and how many; and whether he could state why the National Dental Association, an organisation which represented at the present moment over 300 unregistered dental practitioners, who each, by the terms of his agreement with the association on assuming membership, undertook not to canvass or advertise for patients, and made a declaration that he had been in practice for a period of five years as a dental assistant or practitioner wholly engaged in operations on the mouth before Feb. 5th, 1919, had not been accorded equality of treatment with the Incorporated Dental Society, Ltd.—Dr. ADDISON replied: No, Sir; most of the proposals referred to in the Report of the Committee must form part of the general scheme for improved health services for the nation which the Ministry of Health are concerned to develop as soon as possible, but there has not yet been sufficient time to work out such a scheme, nor to consider adequately the various recommendations of the Committee in question as regards dental registration. The other points in the question, therefore, do not arise.

THURSDAY, JULY 17TH.

### Paddington Military Hospital.

Captain WEDGWOOD BENN asked the Secretary for War whether he was aware that upwards of 500 wounded men, the majority of whom were cases that had lost one or more limbs, had recently been transferred from various military hospitals, in particular from the King George Hospital, to the Paddington Military Hospital, in the Harrow-road; whether he was aware that the Paddington Military Hospital, a converted workhouse, was quite unsuited for the reception of such cases both by construction and situation.—Mr. CHURCHILL replied: Complaint has been made, especially regarding the situation of this hospital, and for sometime past endeavours have been made to obtain another suitable building, but, I regret to say, so far without success. I hope, however, that arrangements may be made to enable the hospital to be vacated within the next few weeks.

### Disturbance of Military Patients.

Major GLYN asked the Secretary for War if the position of those officers and men who were at present undergoing treatment in those military hospitals that were to be taken over by the Ministry of Pensions on August 1st had been fully considered; whether it was proposed that patients were to be removed from those hospitals to others remaining under War Office control, in spite of the fact that their treatment was liable to be detrimentally affected if such transfer to nurses, doctors, and surgeons who had not supervised their cases from the first was carried out; and whether it was possible for the War Office and the Ministry of Pensions to come to such a financial understanding in regard to these cases that would permit these patients to remain undisturbed and to continue their treatment under the existing medical and nursing staff.—Mr. FORSTER (Financial Secretary to the War Office) replied: No transfer will take place when injury to the patient's health would be likely to be caused thereby.

### Veneral Disease.

Mr. LUNN asked the Minister of Health whether inquests were required to be held after all cases of sudden death of persons undergoing treatment for venereal disease; and, if not, whether he would issue instructions with a view to

securing that inquests should be held on all such cases in future.—Dr. ADDISON replied: Section 2 of the Coroners Act, 1887, requires an inquest to be held whenever there is a violent or unnatural death, or a sudden death of which the cause is unknown. There is no power under the statute enabling any Minister to issue instructions that inquests shall be held in any cases not covered by the section to which I have referred.

MONDAY, JULY 21ST.

### Invalided Officer: Statement by Pensions Minister.

Mr. BOTTOMLEY asked the Pensions Minister whether he would give an explanation of the circumstances in which a lieutenant invalided out of the Army suffering from neurasthenia was recently directed by telegram, sent to a hotel at which he was staying, to proceed to the London Lock Hospital, Harrow-road, which was an institution for women suffering from venereal disease; whether, having been certified by two medical men employed at his own expense as free from such disease and having protested against being sent to the men's branch of the Lock Hospital, situated in Soho, to which he had been referred from the women's institution, he was informed by the Ministry of Pensions that an officer's unreasonable refusal to undergo treatment rendered him liable to have his pension reduced by half; whether he would say who was responsible for this course of action; and what reparation was being made to the officer in question.—Sir L. WORTHINGTON-EVANS replied: I am glad to have the opportunity of expressing publicly my deep regret for the annoyance and trouble given to this officer. The doctors are not able to decide affirmatively what is the cause of his illness. He was sent to a tuberculosis specialist and examined by him, but the report was negative; he advised that the officer should be admitted to hospital and kept under medical observation in case the illness was occasioned by general paralysis. Arrangements were made for a private room at the Lock Hospital, where it was intended that the specialist in general paralysis should make the desired observations so as to exclude general paralysis, as tuberculosis had been excluded, if such turned out to be the case. The telegram never ought to have been sent, although no serious consequence would have arisen if it had been opened by the officer. It was, however, opened at his request and read to him on the telephone by someone at his hotel. With regard to the letter the officer came to the Ministry after the letter was written and before it was delivered and saw one of the doctors. The doctor heard his explanation and withdrew the letter and apologised for the telegram. The letter ought not to have been sent, but being in the post could not be recalled. There was no question of unreasonable refusal to undergo treatment; no treatment had been decided upon. The officer was asked to go to the hospital for observation. Treatment could not be decided upon until after the result of the observation was known. The officer himself has since proved that there is not the slightest reason to suppose that he is suffering from general paralysis due to venereal disease. I fully accept that conclusion. The clerk at the Ministry who was responsible for the letter will not in future be engaged in this class of work, and steps have been taken to ensure that no warnings of withdrawal or reduction of pension shall be made until the case has been considered by a principal medical officer. I have myself seen this officer when he called at the Ministry. I have expressed to him my deep regret for both the telegram and the letter, and I have offered to refund to him the expenses to which he has been put in obtaining the medical certificates referred to. I explained to him what I have now told the House, and I trust that the blunder made by an administrative clerk will not discredit the really excellent and efficient work done for thousands of officers and men by the medical officers employed at the Ministry.

TUESDAY, JULY 22ND.

### Case of Paralysis Agitans.

Mr. RAPER asked the Financial Secretary to the War Office if he would state what steps were being taken definitely to settle the compensation claim of Mr. Thomas Clark Barcliff, in view of the fact that Mr. Barcliff had been discharged as incurable from five hospitals and had also been declared to be suffering from paralysis agitans by every nerve specialist who had examined him.—Mr. FORSTER replied: Mr. Barcliff has received the maximum compensation payable under the scheme framed under the Injuries in War Compensation Act, 1914 (Section 2), which applies to his case. In the opinion of the Treasury medical referee Mr. Barcliff would benefit from a course of special treatment suitable for the malady from which he is suffering, and arrangements are being made for him to receive such treatment.

### National Health Insurance Bill.

The House considered on Report the National Health Insurance Bill, which had passed through Standing Committee without amendment. The Bill was read a third time.

## Medical News.

**UNIVERSITY OF CAMBRIDGE: THE PSYCHOLOGICAL LABORATORY.**—It has been decided by the managing committee for the Cambridge diploma in psychological medicine to recognise 12 months' clinical experience in a military neurological hospital as qualifying a candidate to enter for Part II. of the examination for this diploma. Part I. is open to all persons whose names are on the Medical Register. A course in preparation for these examinations will be held at the psychological laboratory, Cambridge, during August next. Information may be obtained by writing to Dr. J. P. Lawson, at the Psychological Laboratory.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**—An extraordinary Comitia of the Royal College of Physicians of London was held on July 17th, Sir Norman Moore, the President, being in the chair. A letter was received from the Minister of Health, dated July 4th, inviting the College to place before him the names of persons who, in the opinion of the College, are specially suitable to serve upon the Consultative Council which will advise upon "Medical and Allied Services." A provisional list was laid before the College and approved.

**LONDON UNIVERSITY.**—The Senate has sanctioned the granting of the M.S. degree in two additional branches—namely: (1) ophthalmology; and (2) laryngology, otology, and rhinology; and the regulations have been modified in accordance with this decision.

**UNIVERSITY OF EDINBURGH.**—At the summer graduation ceremony held on Thursday, July 10th, in the M'Ewan Hall, Edinburgh, the honorary degree of Doctor of Law was conferred upon Sir Thomas R. Fraser, F.R.S., emeritus professor of materia medica in the University, and upon Mr. Rutherford Morison, lately professor of surgery in the University of Durham.

The following degrees in Medicine were awarded:—

### DOCTOR OF MEDICINE.

\*Arthur Cecil Alport (in absentia), †Robert George Archibald, \*Robert George Baerman, Frederick Adolphus Fleming Barnardo (in absentia), †Edwin Bramwell, Frederick Russell Bremner (in absentia), Arthur William Tremblheere Bulst (in absentia), †Duncan Macnab Callender (in absentia), \*Disney Hubert Dusch Cran, \*Gerald Fitzgerald, Walter Benjamin Harry, Kenneth Goodall Heaume, James Burnett Hogarth, Matthew James Johnston, \*Robert Lawson, Edward Loggie Middleton, Ronald Roderick Murray (in absentia), \*William Henry Parkes (in absentia), Dhanavada Samuel Ramachandra Rao (in absentia), Archibald Romanes, Alan William Stuart Siebel, Robert Scott Stevenson, Samuel Henry Stewart, and \*Edmund Leigh White.

\* Commended for thesis. † Highly commended for thesis.

### MASTER OF SURGERY.

James Methuen Graham (awarded gold medal for thesis).

### BACHELOR OF MEDICINE AND BACHELOR OF SURGERY.

Henry Morris Anderson, Adam Armit, Alfred Badenoch, Harry Berelowitz, John James Rouse Binnie, Alice Bloomfield (first-class honours), Charles George Booker, Peter Martin Brodie (second-class honours), Cecil Carron Brown, Robert M'Call, Leybourne Stanley Patrick Davidson (first-class honours), Frederick John Deane, Arthur Armstrong Denham, Robert Lightbody Galloway, Kurt Gillis, Morris Goldberg (second-class honours), Arthur Trevenning Harris, Marjorie Harris, Cecil Edith Lyster Hole, Jiwanda Ram Katarlyia, Marjorie Hamilton King, Raymond Leslie Langley (first-class honours), Robert Kho Seng Lim, Harry Stephenson Lucraft (first-class honours), John Charles Macartney, James M'Intyre, Ella Grace Florence MacKenzie, Ronald Douglas MacKenzie, Robert Macnair, Mona Macnaughton, Elizabeth M'Vicker, Mabel Stevenson, Martin, George Henry Hope Maxwell (in absentia), Jacobus Hugo Meiring, Abraham Marais Moll, John Oliver Murray, Arthur Vincent Treadwell Musto, Edward Paul O'Dowd, Aerath Nanyanan Nanoo Panicker, Clifford William Patterson, John Redwood Payn, Howard Sidney Plozman, Eric Haldane Ponder, Mary Simpson Poole (née Paterson), William Gordon Robson (second-class honours), Beatrice Annie Sybil Russell, Richard Sandilands, Mahmoud Zaky Sheriff, Bertie Soutar Simpson, William Augustus Slack, Valentine Alexander Stooks, Arthur Kinsey Towers, Maung Sein Tun, Petrus Cornelius Uys, Jakob Rudolph de Villiers, George Ronald Waller, Robert Boog Watson, Alfred George Norton Weatherhead, John Sinclair Westwater, James Leslie Wilson, and Duncan Ferguson Yuille.

**SUMMER SCHOOL OF CIVICS AND EUGENICS.**—The second Summer School of Civics and Eugenics, organised by the Civil and Moral Education League and the Eugenics Education Society, will be held at Cambridge during the fortnight from Saturday, August 2nd to 16th. The aim of the school is to give teachers, social workers, and others interested in educational and social reconstruction opportunities for study and discussion. The fee for the fortnight's course is 2 guineas. Board-residence varies from £2 2s. to £3 3s. The committee have at their disposal a small bursary fund, which is to be used to cover the expenses of such people as find themselves unable to defray the whole cost of their course at the school. Further particulars can be obtained from the Summer School Secretary, 11, Lincoln's Inn-fields, London, W.C. 2.

**QUEEN'S UNIVERSITY OF BELFAST.**—The Senate of Queen's University of Belfast on July 16th appointed Mr. A. W. Stewart, D.Sc., professor of chemistry, in place of the late Dr. A. Letts; Dr. Thomas Walmsley professor of anatomy, in place of Dr. J. Symington, resigned; and Dr. J. W. C. Gunn lecturer in pharmacology, in the vacancy created by the retirement of Sir William Whitla. All these new teachers come from Scotland, the first two from Glasgow University, the third from the University of Edinburgh. Dr. P. T. Crymble has been reappointed lecturer in applied anatomy. It was announced at the meeting that a sum of £8000 is to be placed by the Treasury at the disposal of Queen's University for expenditure during the current financial year on certain pressing wants (salaries of professors and lecturers, urgent improvements in various teaching departments, &c.). So far, it was said, no actual money had passed from the Treasury to the finance committee of the University.

**DEVON RED CROSS AND VOLUNTARY AID ORGANISATION.**—During the late war this association was responsible for the organisation of 34 hospitals and equipped 3905 beds, which received 45,007 patients, with a staff comprising 2735. The funds administered amounted to £261,585, the cost of administration being £1912.

**BOGNOR WAR MEMORIAL COTTAGE HOSPITAL.**—The Bognor War Memorial Cottage Hospital, towards which Mr. James Fleming gave £7000, was opened on July 16th. After a short dedication service Mrs. Fleming was presented with a silver key, with which she unlocked the door amid an enthusiastic scene. The hospital was formerly a large residence situated on the Chichester-road, and the greater part of the £7000 has been spent in its conversion into a hospital of 5 wards and 15 beds, with, of course, all the necessary concomitants. A roll of honour carved in oak, which will bear the names of all those from Bognor who have fallen in the war, has been placed in a conspicuous position in the entrance hall.

Dr. C. H. Browning, director of the Bland-Sutton Institute of Pathology at the Middlesex Hospital, has been elected to the Gardiner Chair of Bacteriology in the University of Glasgow.

**CROWNHILL CONVALESCENT HOME, NEAR PLYMOUTH.**—The annual meeting of the friends of this institution was recently held under the presidency of Lord Mount Edgumbe. It was stated that during the past year 149 patients had been admitted, about half the number in pre-war days. The financial statement was satisfactory. The chairman alluded to the excellent work of the home and reminded the subscribers that the charming building had been presented by Dr. C. A. Hingston.

**THE LATE DR. B. A. PALMER.**—The death is announced of Benjamin A. Palmer, M.B. Glasg., J.P., of Millvale House, co. Armagh, in the Newry Hospital. Dr. Palmer, an Armagh man, was born on March 30th, 1852. He studied in Glasgow, where he graduated M.B. in 1880 and became also L.R.C.S. Edin. In the same year he was appointed dispensary medical officer of the Crossmaglen District of the Castleblaney Union, a position he occupied until 1890, when he became medical officer of the Mullaghglass Dispensary District of the Newry Union, an office he held at the time of his decease. For over 33 years he was a justice of the peace for county Armagh, and for 11 years for the county of Down. Dr. Palmer was a well-known and much respected figure in the life of Newry and the surrounding district, and a large circle of friends and patients now mourn his loss. He leaves a widow and three daughters.

## Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions and others possessing information suitable for this column, or invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

BANFORD, Miss A., has been appointed House Surgeon to the North Devon Infirmary, Barnstaple.

GEFFEN, D. H., M.B., B.S. Lond., Second Assistant Medical Officer to the Marylebone Guardians.

GLAISTER, J., M.D. Glasg., one of the Medical Referees under the Workmen's Compensation Act for the Sheriffsdoms of Ayr, Renfrew and Bute, and Stirling, Dumbarton, and Clackmannan.

HALLONS, NORMAN F., M.D. Oxon., D.P.H., Medical Officer to Marlborough College, Wilts.

WADE, R., M.R.C.S., I.R.C.P., Assistant Administrator of Anæsthetics to St. Bartolomew's Hospital.

Certifying Surgeons under the Factory and Workshop Acts: ROBERTS, A. H., M.R.C.S., L.R.C.P. Lond. (Malling); WALKER, W. N., M.B., Ch.B. Dubl. (Manorunningham and Letterkenney); WATSON, F. H., M.B., B.C. Cantab. (Sheerness).

## Vacancies.

For further information refer to the advertisement columns.

- Barnsley, Beckett Hospital.—First and Second Res. 11 S's.  
 Bermouth Medical Mission for Women and Children.—Med. Woman. £150.  
 Birmingham City.—Municipal Bacteriologist. £700.  
 Birmingham General Hospital.—Asst. P. £50 Surgical Registrar. £200. Two Asst. S. £50. Also H.P. H.S., Obstet. H.S., H.S. to the Ear and Throat and Venereal Dept. £100.  
 Birmingham, Rubery Hill Asylum and Annexe at Hollymoor.—Med. Supt. £1250.  
 Bolton, Townleys Hospitals, Farnworth, near Bolton.—Med. Supt. and Asst. Med. Supt.  
 Bournemouth, Royal Victoria and West Hants Hospital, Boscombe Branch.—Res. M.O. £250. Also Second Res. M.O. £200.  
 Cairo, Egyptian Government School of Medicine.—Professors and Lecturers. ££1000 and ££600. Also Radiologist and Lect. in Radiology, ££550, Anaesthetist and Lect. in Anaesthetics, ££500, and Registrar and Tutor, ££600.  
 Canterbury, Kent and Canterbury Hospital.—Jun. Res. M.O. £150.  
 Cape Town University, Faculty of Medicine.—Profs. of Medicine, Surgery, Obstetrics, and Gynaecology. £1250.  
 Cardiff, Glam. Ely Hospital.—Asst. Res. M.O. £300.  
 Cheam, Surrey, St. Anthony's Hospital.—Res. M.O.  
 Coventry and Warwickshire Hospital.—Hon. Surg. Staff.

 Smyrna Mission and Beaconsfield Memorial Hospital.—Medical Missionary. £250.  
 Taunton and Somerset Hospital.—Hon. S.  
 Taunton, Somerset and Bath Asylum, Gifford.—Asst. M.O. £300.  
 Tynwald, Whiteness, and Weisdale Parish.—M.O. and Pub. Vac. £45.  
 Twickenham, St. John's Hospital.—Hon. Con. Surgeon.  
 West African Medical Staff.—Number of appointments. £400.  
 West Riding County Council, Treatment of Venereal Diseases.—Asst. £550. Also Sch. Oculist. £450.  
 The Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Soham (Cambridge).

## Births, Marriages, and Deaths.

### BIRTHS.

HARNETT.—On July 16th, at Devon House, Barnet, the wife of W. G. Harnett, M.A., M.D., of a son (stillborn).

### MARRIAGES.

DUNCAN—McEWAN.—On July 22nd, at St. Wilfrid's Church, Harrogate, William Henry Duncan, F.R.C.S. Edin., to Ida, elder daughter of Mr. and Mrs. J. H. McEwan, Crimble House, Harrogate.  
 ORR-EWING—ROSS.—On July 16th, at Parbold, Archibald Orr-Ewing, M.B., B.C. Cantab., to Gladys Mary, second daughter of Mr. and Mrs. Alex. Ross, of Clifton, Parbold.

### DEATHS.

PEILE.—On July 14th, at Phillimore, Sidmouth, William Hall Peile, M.D., aged 50.  
 RANDALL.—At Park-street, Bridgend, Wyndham Randall, L.R.C.P. Edin., M.R.C.S. Eng., in his 73rd year.  
 N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments, and Answers to Correspondents.

### THE BATHS OF OLD LONDON.

By SEPTIMUS SUNDERLAND, M.D. BRUX.

#### PART III.

#### Spas, Wells, and Springs.

THE preceding account of the few baths of Old London, the former existence of which I have been able to trace, will be sufficient to show that some attempt was made to treat diseases of the skin by balneo-therapeusis in London during the past few centuries.

#### Spas.

But there remains something to be said about the spas and wells of Old London in connexion with bathing. During the time when existed the vogue of drinking the waters at the various London spas—roughly speaking, from the latter half of the seventeenth to the early period of the nineteenth century, no provision was made for bathing at these spas with the exception of one or two minor ones already mentioned; although in many instances, no doubt, the water was used locally by affusion. Those best known of the spas (the waters being taken internally) were: St. Chad's for "scrofula" (near the present King's Cross); Pancras, for "obstinate cases of scurvy, king's evil, leprosy, and all other skin diseases"; Powis Well (near the Foundling Hospital, Guilford-street), for "sore legs, inflammation of the eyes"; Sadler's Well for "scurvy"; Shadwell Spa for "scorbutic and cutaneous diseases" (by drinking or bathing); Hoxton Well for "those afflicted with wounds, ulcers, fistulas, sores, scabs, sore eyes, sore legs, leprosy," &c.; Marylebone Spa for "scorbutic disorders"; The Well in Restoration Spring Gardens (St. George's Fields) "for the cure of all cancerous and scorbutic tumours"; St. George's Spa, Lambeth, by Dr. John Fothergill in 1695 for "most cutaneous disorders and preventing cancerous affections"; Biggin Hill Spring, Norwood, for "scrofulous complaints." Sydenham Wells were referred to by Dr. John Peter as Lewisham Well. He wrote:—

"This water outwardly used is very good for most cutaneous distempers as leprosy, itch, scabs, pimples, ringworms, scurvy. It also dissolves tumours, and cureth old ulcers if the parts ill-affected be washed or bathed therewith, or if a curd made by boiling milk therewith be applied; and I am persuaded, it being used by way of a warm bath, it would be of great efficacy to consume hydropical tumours, to ease or cure gouty and rheumatic dolours, as I far more effectual also in the above-said cutaneous distempers."

#### Springs and Wells.

Other old springs and wells of London which may be mentioned as having some connexion with the subject of dermatology, although they did not achieve the fame of being considered "spas," or even "spurious spas" are the following: "Crowder's Well (Cripplegate) "for sore eyes"; Highgate Spring "for bathing eyes"; St. Agnes Well, Hyde Park, "for bathing eyes"; Vauxhall Well "for eye troubles"; Ladywell, Lewisham, "for sore eyes"; East Sheen Well "for eye troubles and for bathing the legs."

#### Holy Wells.

I will not weary you by enumerating the names of the 23 so-called "Holy Wells" of London, about which I gathered information some years ago, although, of course, all the "Holy Wells" were attended by people suffering from skin troubles as well as from every other ailment.

#### Conclusion.

I do not know to what extent ordinary bathing and washing may prevent the acquirement of skin diseases, but assume that most modern dermatologists agree with Crocker's statement in the 1903 edition of his book that "the key-note of modern dermo-therapeutics is antisepticism." I imagine, therefore, that skin specialists approve of ordinary bathing and washing in moderation for people with healthy skins, with the hope of prevention of some at least of the various cutaneous disorders, in spite of the views of Dr. Samuel Johnson and of the apostle of the doctrine of vaccine treatment. Of course, everyone knows that bathing to excess and the use of certain soaps may cause skin irritation.

At the present day the value of bath treatment in phases of certain skin diseases is recognised and is recommended by dermatologists, but not, perhaps, to the extent that it may deserve. It is possible that in the near future, when the practice of hydrology will be systematically taught either in post-graduate courses or as part of the medical student's curriculum, that the attention of skin specialists will be still more directed to the subject, and that hydrological methods of treatment may be elaborated which will be even more beneficial to sufferers from skin diseases than those practised at the present time.

In conclusion, I should like to offer the suggestion that it might be advisable that a fuller investigation should be made by dermatologists on the effects of bath-treatment in skin diseases. It appears to me that its value may not be adequately recognised, that its possibilities may not have been sufficiently explored, and that no very earnest endeavours have been made of late years to attempt further progress.

To the Editor of THE LANCET.

SIR,—My good friend Septimus Sunderland, in his excellent description of the baths of Old London, refers to the bath in Strand Lane as a "Roman bath." In doing this he is only voicing the commonly received opinion. There is, however, no evidence that the bath dates back to Roman times. It does not resemble a Roman bath, which was, I believe, usually a square excavation in the floor, lined with tessellated pavement, and descended into by one or more steps; whereas the bath in Strand Lane, as Dr. Sunderland points out, resembles the ordinary plunge bath of modern times, but of large size. Moreover, it is very strange, as pointed out by Besant and others, that, if this bath is Roman, it is not mentioned by Stow and other antiquaries.

I am, Sir, your faithfully,  
S. D. CLIPPINGDALE.

Holland Park-avenue, W., July 21st, 1919.

#### HEALTH OF THE GERMAN NAVY DURING THE WAR.

WITH a few noteworthy exceptions German ships stayed in port during the war, so that the conditions of health obtaining among the personnel cannot have differed greatly from those of peace times. The daily ration strength of the German navy—the number of men in that navy—is calculated<sup>1</sup> to have been in the first year of the war, 202,123; in the second, 235,267; in the third, 254,347; and in the fourth, 383,071 men. Amongst these there came under treatment in each year ("new cases") per 1000, first year, 472; second year, 442; third year, 441; and fourth year, 497. As the average annual number, per 1000, for the five years before the war was 525, it appears that fewer men fell sick in the German navy in war than in peace. The increase in the figures for the fourth year is largely due to the influenza epidemic (92 cases per 1000). Tuberculosis of the lungs is the only disease quoted as more prevalent during the war (per 1000 before the war, 1.37 cases annually, during the war in successive years 1.45, 2.06, 2.81, and 2.09), while the mortality, too, was much increased (11.1 per cent. in the first year, 10.4 in the second, 13.6 in the third, and 18.4 in the fourth year) (August, 1917–August, 1918). The number of men killed at once, without medical treatment, is not mentioned, but of the sick and wounded who were seen by doctors 4073 died; also 5899 were invalided up to August 1st, 1918.

#### THE GAZETTE OF THE THIRD LONDON GENERAL HOSPITAL, WANDSWORTH.

AMONG the many publications which the various war hospitals have issued for the benefit of the patients and the amusement of both patients and public, the *Gazette* of the 3rd London Hospital holds a prominent place, and it is with feelings of regret that we announce its forty-sixth and last number, though that regret is tempered by the fact that the signing of Peace has rendered the hospital no longer necessary. The hospital, which has done most excellent service for the wounded, had from the first a wealth of artistic and literary talent among its staff and patients, and the *Gazette* has borne witness to the lavish way in which that staff has placed its talents at the disposal of the patients, and in providing for them and the public, under the past and present editors, Corporal Ward Muir and Sergeant Noël Irving, a magazine of high merit. This last and enlarged number maintains that high standard, and both as a souvenir of Peace and an entertaining journal is more than worth the 1s. which is charged for it. Many of the old contributors cater for this issue, Corporal J. H. Dowd illustrating among other productions the emotions of a hospital visitor on receiving final instructions from a disabled patient as to the writing of a letter: "Love to yourself and Bahs. P.S. Please excuse the scribble."

#### COLONIAL HEALTH REPORTS.

*Gilbert and Ellice Islands.*—According to the official report for 1917–18 there were during the year in 12 of the islands of the Gilbert Group, having a population of 18,014, 579 births and 528 deaths. In two of the islands the deaths exceeded the births, there being 64 deaths to 44 births in Butaritari (population 1133) and 63 deaths to 25 births in Oceau Island (population 1100). In the latter instance the high death-rate, it is suggested, is largely due to the unnatural conditions under which the natives live and to the use of European foodstuffs, whilst the low birth-rate is attributed to "the scarcity of wives among the company's labourers."

In seven islands of the Ellice Group (population 3131) there were 171 births and 95 deaths. Fanning Island reported 17 births and only 3 deaths. From certain other islands returns have not been received. The erection of the Central Leper Asylum on the island of Tarawa has been completed. It has not as yet been found possible to collect the lepers from the other islands owing to the lack of a Government vessel. Efforts are being made to charter a leper vessel from Australia. A suggestion has been put forward for an improved Government hospital for Ocean Island and for a water-borne drainage system for the native villages and Government station. The continued prevalence of dysentery on Ocean Island is causing anxiety. The native death-rate on that island is far too high, especially amongst the resident population as opposed to native imported labour. The following record of the rainfall at Ocean Island for the last five years shows the remarkable variation on the Line Islands:—

	Inches.		Inches.
1913-14 .....	131.05	1916-17.....	6.63
1914-15 .....	137.85	1917-18.....	26.62
1915-16 .....	18.41		

The drought broke in May, 1918, and in the last two months of the year some 20 inches were recorded.

#### THE NATIONAL COUNCIL FOR THE UNMARRIED MOTHER AND HER CHILD.

THE annual report of the first year's work of this Council shows useful progress. The legal recommendations on the preventive side of the work as laid down at the Mansion House Congress in 1918 have resulted in the drafting of a Bill which is likely to form the basis of legislation, while the provisions of the Maternity and Child Welfare Act open up unlimited opportunities for the curative side of the work. Prejudice remains in certain quarters against helping the unmarried mother, but it is noteworthy that the constructive policy of the Council has evoked a large measure of sympathy in the efforts made to restore the mother to good citizenship, and to make effective the responsibilities of the father. The greater activities of the Council depend upon increased financial support, but, as at present constituted, the Council has no reliable source of income. Since its inception the work has depended very largely on the generosity of the honorary treasurer, Sir Charles Wakefield, but if the work is to continue generous financial help must be given. The British Red Cross Society has, we are glad to note, accepted an invitation to join the Central Council for Infant and Child Welfare, of which the National Council for the Unmarried Mother is a constituent part.

J. R. L. is advised to take counsel with one or two professional colleagues before acting.

*Prevention of Hydrophobia.*—A person who talks of the arguments of opponents as "imbecilic rot," and who states that "Pasteurism (*sic*) has been proved an utter imposture," clearly needs no reply.

# An Address

ON

## X RAY THERAPY.

*Delivered before the Hampstead Medical Society*

By ROBERT KNOX, M.D. EDIN., M.R.C.S., L.R.C.P.,  
CONSULTING RADIOLOGIST, GREAT NORTHERN CENTRAL HOSPITAL;  
HONORARY RADIOLOGIST, KING'S COLLEGE HOSPITAL; DIRECTOR,  
ELECTRICAL AND RADIOTHERAPEUTIC DEPARTMENT,  
CANCER HOSPITAL (FREE) LONDON.

MR. PRESIDENT AND GENTLEMEN,—The proper appreciation of the value of radiations in practical therapeutics is, to those unacquainted with the subject, very difficult. Opinions vary amongst surgical and medical experts to an astonishing degree. Such opinions are sometimes expressed on scanty knowledge of the matter, especially of the technique and the action of radiations upon the tissues, and oftener on the results obtained in the treatment of quite unsuitable cases. Perhaps a still more confusing factor is presented by the conflicting opinions of experienced radiologists who may be over-enthusiastic in their claims for the efficacy of the agents they employ, and who may not have had a very extensive clinical knowledge of the diseases they are called upon to treat. Lastly, the new agents were quite early in their history called upon to cure diseases which had completely baffled all other known methods. Little wonder that the results should have been scanty, and that so many conflicting opinions on value have been formed and expressed.

In this paper I shall endeavour to give a summary of X ray therapeutics and describe the technique for a number of diseases which benefit from radiation treatment. It will be impossible to discuss the instrumentation or the physics of the subject. The former is best learned by a few visits to an X ray department. The latter calls for an extensive practical knowledge of physics.

### THE X RAYS AND THE STRUCTURE OF MATTER.

The far-reaching effects of the discovery of X rays and the subsequent isolation of radium were at the outset hardly recognised. Kaye, in his introduction to his admirable book on X rays, says:—

"In the early nineties it was not infrequently maintained that the science of physics had put its house in complete order, and that any future advances could only be along the lines of precision measurement. Such pessimism has been utterly confounded by a sequence of discoveries since 1895 unparalleled in their fundamental nature and promise. Even many not specially concerned have had their attention directed to the recent attempts at solving the riddle which has excited interest and taxed ingenuity since the beginning of civilisation—the problem of the ultimate structure of matter.

The chemist and physicist have long built upon a theory of atoms and molecules, though information as to the existence and behaviour of individual atoms was only based on speculation, however justifiable.

But within the last decade we have not only isolated the atom but we have learnt a great deal about its internal structure. Radio-activity has, for example, introduced us to an electrically charged atom of helium (the  $\alpha$  ray) with characteristics such that it can, in spite of its extreme smallness, make individual appeal to our senses.

The speed of the  $\alpha$  rays is so abnormally high that, if, for instance, they are allowed to strike a fluorescent screen, as in the spintharoscope of Sir William Crookes, each atom possesses enough energy to record its arrival by a single flash of light. Rutherford and Geiger have actually recorded the arrival of atoms by means of a delicate electrometer. C. T. R. Wilson has succeeded in rendering visible and photographing the paths, not only of single charged atoms but of electrons and X rays as well.

These are interesting phenomena, and the closer study of their production and characteristics led to the further discovery of electrons by J. J. Thomson and of the X rays by Röntgen.

Through the efforts of a band of workers the Röntgen rays have thrown a search-light on many phases of atomic physics not susceptible to other methods of attack. Quite recently X rays have come to the aid of the crystallographer and displayed in the hands of Laue, Friederich and Knipping, Bragg, and others, the regular grouping of the atoms in a crystal.

The Geissler discharge tube known as the Plücker Hittorf or Crookes tube—the former beautiful plaything of the scientist—has proved the pioneer of some of the most wonderful discoveries and speculations that physical science of this or any generation has known."

That is, in brief, a summary of the events leading up to, and including, the discovery of X rays. These have, as can readily be seen, revolutionised our conception of the atom.

### ACHIEVEMENTS AND POSSIBILITIES OF RADIATIONS IN MEDICINE.

The great advances in physics rendered possible by the accidental discovery of X rays by Roentgen have their analogues in the field of practical and experimental medicine. The immediate adoption of X rays all over the world by medical men working with physicists soon led to an appreciation of the value of the new agent.

No one at the outset could have foretold the immense strides the new agent would make in the short space of two decades. The use of X rays in diagnosis has been increased, and many important advances have been made as experience accumulated and apparatus was improved.

Far more interesting has been the gradual unfolding of the possibilities of radiations in therapeutics. The developments up to the present have been enormous. Still greater discoveries may lie before us, especially when, as a result of more extensive and intensive research, better understanding of the method of action of radiations in their application to the treatment of disease is arrived at.

It is necessary to indicate the ever-increasing field of activity before we attempt to deal with the technique and description of cases suitable for treatment. X rays when skilfully used can influence practically all the tissues which go to make up the living organism, the degree of action depending solely upon the quantity of radiation used and the response to it of the tissue affected. Here we have the possibility of acting upon one or all of the tissues by an agent of great power. Obviously the action must be a general one, whose activities are at present only vaguely understood. So far we know that definite results follow upon definite doses of radiations, and if this fact is grasped we go a long way towards a comprehension of the governing principle of radiation therapeutics.

Medicine, however, is not an exact science, and rules or laws which have a definite value in physics are not so readily applied to the practice of medicine. So far the applications of radiations in medicine are more or less empirical.

As already stated, the striking discoveries in physics have gone a long way towards explaining problems which have perplexed the human mind since the dawn of early civilisation. Possibly when our knowledge extends, and a thorough grasp of the physics of these agents and the underlying principles which govern their action has been obtained, it will lead to the development of a thorough technique and to a great improvement in the results obtained by their application to morbid conditions.

The developments may even be as revolutionary in medicine as they have been in physics. It may be even that the discovery of an underlying principle in cell metabolism may give us (by the aid of physics) the clue to the causation of certain diseases which have been the torment of many generations of medical men. Certainly the future teaching in the medical sciences must take more notice of physics. Medical education may be revolutionised in this way, and many of the now recognised and apparently well-established laws in medicine may, in the light of further research, require to be reviewed and possibly seriously modified.

### EFFECTS OF RADIATIONS ON THE LIVING CELL.

A great deal of valuable work has already been done in regard to the behaviour of the living cell when exposed to radiations. Colwell and Russ have given us a valuable work in "X rays, Radium, and the Living Cell," which clearly sets forth the great effect which can be produced by radiations on cellular structures.

A thorough appreciation of the action of radiations upon the normal tissues will be valuable when we come to deal with morbid conditions. What we know now is very limited, and the result of the application of measured doses. Dealing with the subject broadly, it may be stated that if a particular cell or a group of cells be exposed to a beam of radiations

from any source, and in this example we will assume that the radiations emanate from an X ray tube, certain events may follow: (a) The cell may be stimulated; (b) its activities may be inhibited; (c) the cell may be destroyed.

The determining factor in the production of any of these ends so far as the radiations are concerned is the intensity of the radiation and the duration of the exposure. The former is governed by certain physical data which it is unnecessary to enumerate now.

In regard to the cell, the determining factor will be the resistance the cell possesses to external stimuli. Cells vary enormously in this respect, and, further, individual cells of the same type vary in a direct ratio to the stage of activity they are in when treated by the radiations. This is, in fact, the most difficult of the problems one encounters when estimating dosage.

It can readily be seen from a consideration of these facts how many and varied may be the results from a single exposure to radiations. It also indicates that treatment by radiations must of necessity be solely in the hands of experts whose training will enable them to obtain the maximum of good, and, what is of equal importance, the minimum of harm in the treatment of diseased conditions.

It is clearly demonstrated that changes can be induced in cellular structures, and these might be described as the direct effects. There are, however, *indirect effects* produced which may have a far-reaching influence upon the metabolism of the organism. The human frame is a complex machine with many systems in full activity, each acting in sympathy or coördination with the others. Consequently when a particular group of cells which go to make up the area treated is acted upon by a measured dose of radiations various effects of an indirect nature are induced. If the dose is excessive, cell activity is arrested and the cellular structures die. The destroyed cells are absorbed or rendered inert by the activity of the surrounding tissues. When absorption takes place the products of disintegration are carried by the lymphatics to other organs in the body. Far-reaching effects may follow. The term "reaction" is applied to this phenomenon. The reaction may be severe and a rise of temperature lasting for several days may occur. This is obviously due to a powerful action upon the tissues. Products of disintegration of tissues may be circulated in the blood and serum and produce beneficial or harmful effects. If the former, the tissues are toned up and the patient improves. If the latter, the patient may be reduced to an extreme degree. This is specially liable to occur in the treatment of diseases of the blood, such as leukaemia, where, if care is not exercised, a rapid fall of the white cells may lead to a fatal leucopenia.

There are many interesting phenomena induced by radiations which could be discussed at great length, but time forbids.

In dealing with a subject of such scope and interest it is somewhat difficult in a single lecture to give an adequate description of all the points of interest, and much of value must be left to another occasion. What, I imagine, will be of the greatest value will be a brief consideration of the practical application of radiations to the treatment of disease, with short descriptions of technique and a summary of the value of the radiations in their application to particular diseases. These are numerous, since, as has been shown, X rays may influence practically all the tissues which go to make up the complex mechanism of the human frame.

#### THE TREATMENT OF DISEASES OF THE SKIN.

The diseases of the skin are particularly responsive to regulated doses of X rays. The proof of this lies in the fact that many skin specialists include in their armamentarium an X ray outfit, and, judging from the results produced by its use, it is not the least valuable of the agents employed. The treatment of skin diseases by X rays has led to the production of the radio-dermatologist, because it is evident that in this branch of medicine there is ample room for another specialist. I shall, therefore, not labour the point.

Suffice it to state that in the treatment of *ringworm of the scalp* X rays are very valuable. The technique has to be very thorough to produce accurate results. The method is not free from danger. Untoward results are not unknown. These are dermatitis and permanent alopecia. In view of the possibility of such results it is well to caution the

parents of children undergoing X ray treatment that there is danger. The percentage of accident is small but it does occur, and we must admit the possibility of such regrettable consequences. The technique is readily carried out. The following diagram illustrates the manner in which the treatment is administered.

Diagram showing centres of areas to be rayed.

Dr. Adamson is responsible for the introduction into this country of a method of exposure which in skilled hands yields satisfactory results. It consists briefly of the division of the scalp into five areas, each of which gets a measured dose. The diagram shows four of the areas marked on the scalp; the fifth is given to a corresponding area opposite.

A number of other diseases of the skin are amenable to skilfully applied doses of X rays.

*Rodent ulcer* very frequently calls for X ray treatment, and the results are, on the whole, an improvement on those obtained by other methods. Operation offers in the early case a better prospect of cure. X rays, however, quickly heal the ulcer. There is a tendency to recurrence, and it is not at all uncommon for a case to require treatment extending over several years at intervals. On the whole it is better to treat rodent ulcer with radium. The dosage is more accurately controlled, and the results are better and tend to be more permanent.

*Malignant disease of the skin.*—The technique employed should be that for malignant disease generally, though in cases of superficial epithelioma and a number of cases of rodent ulcer unfiltered radiations may be used for the earlier doses, a gradual increase of the thickness of the filter being employed to ensure the adequate irradiation of the deeper structures.

*Hyperidrosis.*—This troublesome condition readily yields to radiations. It should be more widely employed than it is at present. The result can be obtained by one or two large doses at an interval of two to three weeks between the exposures, but it is sound policy to aim at a slower production of the effect. Three or four exposures of each axilla at intervals of three weeks should lead to an arrest of the excessive perspiration. The aim should always be to control rather than to suppress the secretion. The technique is simple. The patient lies on a couch with the arm extended over the head, and the axilla is thoroughly irradiated with unfiltered radiations. Subsequent doses should be given through an aluminium filter.

#### THE TREATMENT OF ENLARGED LYMPHATIC GLANDS.

The growing experience in the treatment of enlarged glands is forcing upon us the conviction that in X rays we possess a remedy of great power. During the course of investigations, extending over many years, into the action of radiations upon tissues, I have found that the behaviour of the enlarged lymphatic glands, of whatever nature, is such as to indicate unmistakably that the effects may be far-reaching. X rays and radium have been extensively employed in these investigations. Either will succeed if the proper

dosage is administered. The response in a large number of cases has been very marked and almost invariable, the chief matter being the selection of the suitable radiation for each condition dealt with.

#### *Diagnostic Value of X Rays in Enlarged Glands.*

It is so certain that several types of enlarged glands will respond to radiations that we might employ the rays in a diagnostic as well as in a therapeutic sense. It has been observed that enlarged glands respond in somewhat like the following order to estimated doses of radiations.

1. Enlarged glands due to simple inflammatory conditions give a very rapid response if suppuration has not set in and the condition is becoming chronic.

2. Lymphadenomatous glands give a fairly rapid response, but not so rapid as the simple inflammatory ones.

3. Sarcomatous and lympho-sarcomatous glands give a rapid response in the majority of cases treated, leading to a rapid diminution in the size, but the effect is rarely permanent, there being a tendency to recurrence, and an ultimate refusal to respond to further treatment.

4. Tuberculous glands give a slow response as a rule. When treated early enough the glands become quiescent and slowly subside, but if not completely fibrosed they tend to break out at a later period.

5. Carcinomatous glands give a very slow response. They hardly ever completely disappear, but they may be arrested in their growth. It is, then, sound practice to remove the glands surgically.

6. Enlarged glands due to a mixed infection are fairly common. For example, in a patient suffering from carcinoma in an adjoining area the glands may enlarge in groups and yet no secondary cancer be present, or the glands on the opposite side from the lesion may become enlarged. These will quickly subside under radiation treatment. All, or nearly all, may disappear, or one or more in a group of enlarged glands may persist. These may ultimately be found to have invading cancer cells in their substance. Only a few groups of cells may be found, the bulk of the enlargement being due to inflammatory reaction, and there may be a secondary infection due to other organisms. The same condition may occur in tuberculosis. A group of glands may have only one or two which are actually invaded by the tubercle bacillus. In both of these instances, if the glands are treated by X rays, a mixed response is obtained.

From a consideration of the above statements it is obvious that in X rays we possess a differential diagnostic test which may be extremely useful when we are in doubt regarding the nature of the causal condition.

#### *Therapeutic Radiation of Tuberculous Glands.*

The irradiation of enlarged tuberculous glands is useful for other purposes than that of the glands alone. Coexistent or chronic tuberculosis of the lungs may at the same time receive benefit from the radiations, and it is a matter for serious consideration whether all such cases should not have radiations applied as a part of the routine treatment.

A considerable amount of this class of work is being done, and it will be interesting to have later a report from sanatoriums which have adopted the method. The general tonic action of radiations should also be helpful in these cases.

The treatment in all cases of enlarged glands must be thorough. In sanatoriums where the patient is at rest and under observation daily doses may be given, a fresh area being selected each day and the exposure repeated to the same area not oftener than once in 14 days. The aim in tuberculosis cases should be to include the thoracic contents, particularly the mediastinal gland, in the field of irradiation, so that all deep glands may receive adequate exposures. In less acute cases the treatment may be given once or twice a week. The dose at each visit will vary with the condition requiring treatment. Tuberculous glands require to be treated for a lengthy period of time extending over many months.

#### ENLARGEMENT OF THE THYROID AND THYMUS GLANDS.

There are no groups of clinical symptoms, such as occur in exophthalmic goitre or Basedow's disease, which call for more skilful treatment than those associated with disorders of the thyroid and thymus glands. The combined skill of the clinician and the radiologist is necessary to combat successfully the complex phenomena exhibited in this

disease. There can be no question that a combined attack, using all the measures available, will enable us to check the symptoms and ultimately cure the disease in a number of cases. These vary in the degree of acuteness, and the treatment will require to be varied accordingly, if a successful issue is to be looked for. Sanatorium treatment combined with medicinal measures and radiations affords us the treatment *par excellence*.

The very acute case demands absolute rest in bed, quiet, careful diet, fresh air, and practically a continuous action from radiation treatment. Small doses of the latter daily may be required over several weeks before any sign of improvement shows itself. Later, when the severity of the symptom abates, the treatment should be gradually diminished in intensity and frequency, and when the metabolic balance is gradually restored the dosage may be reduced to three times a week, and, later, given at longer intervals.

#### *X Ray Treatment in Exophthalmic Goitre.*

Three areas of the thyroid gland should be irradiated, one on the right side, another on the left, and a central large area should include the isthmus of the gland and the upper thoracic region, the object being to include the thymus gland, which is generally enlarged in these cases. Experience has shown the value of including the thymus in the irradiated area. It is well to use filters of 2 or 3 mm. of aluminium, and in addition a secondary filter to protect the skin. The latter should always be carefully protected from over-dosage, because if this should occur, even to a slight extent, it may be followed later by teleangiectasis, which is a troublesome complication.

Treatment should be continued at intervals over a long period of time in these acute cases. Patients complain of a tendency to relapse if this is not done, and it is quite possible to maintain the balance of activity of the gland by such treatment.

Fortunately the majority of cases treated do not require such systematic treatment. There are many patients who are not acutely ill, and though these would improve more rapidly under the stricter regime, circumstances may not allow of such vigorous treatment and it may be necessary to treat these patients at an out-patient clinic. Several hundreds of such cases have been treated by visits of once, twice, or three times a week. The dosage is similar to that described for the more acute cases, and the treatment requires to be carried on over many months. In the majority of cases the progress is satisfactory, there being a gradual restoration of balance of health, a diminution of the symptoms, and a slow but steady reduction in the size of the enlarged gland.

Better results in the more chronic cases have been obtained by the administration of small doses at frequent intervals than were formerly met with when the larger doses were given at intervals of three to four weeks. It is not necessarily cases of very large thyroid glands which respond most readily. The aim of treatment is to regulate the secretion from the gland, and a small gland may be very active. A regulating dose may check the activity, and so influence the condition.

#### *Parenchymatous Goitre and Other Conditions.*

Another form of enlarged thyroid met with is the parenchymatous goitre, where the chief disturbance is due to the enlargement, with few or none of the general disturbances. These cases require careful treatment, the gland being very difficult to treat, and the reduction in size being very slight and very slowly induced.

A number of these cases appear to respond more rapidly when radium is used. Possibly the tissues are more resistant because the enlargement is due to a general increase of the structural tissues as against the glandular hyperplasia with over-secretion in the cases of exophthalmic goitre. In parenchymatous goitre the claim of surgery should always come first in treatment.

Malignant disease is another form of enlargement of the thyroid. This is very untractable to radiation treatment. Operation, if possible, offers the best chance of cure in those cases. Failing this, radium should be used. Large quantities of radium are required, and the filtration should be through 3 mm. or 4 mm. of lead or 2 mm. of platinum, and long exposures given. X rays of a penetrating type may also be useful.

Enlargement of the thymus in children frequently requires treatment. X rays will be found useful in these cases.

### THE TREATMENT OF DISEASES OF THE BLOOD AND DUCTLESS GLANDS.

X rays may be employed in the treatment of a number of these conditions. In dealing with the diseases of organs affected by morbid growths the skin receives a large percentage of the radiation, and it has been noted that in this way the blood while circulating in the tissues receives a dose which may exercise an influence far-reaching in its action not only upon the constituents of the blood but on the tissues through which the blood circulates.

It is, therefore, a good practice to irradiate large areas of skin surface as well as the spleen and the bone marrow when dealing with diseases such as leukaemia. When it is necessary to get a rapid action the greater part of the surface of the body may be utilised for this purpose. Patients who have been treated for other diseases show upon examination a marked improvement in the blood. This is known by an increase in the percentage of hæmoglobin and a raising of the colour index, and if a blood count is taken it may show a marked increase in the percentage of the red blood corpuscles. Patients who have been treated by X rays for fibroid of the uterus frequently show this marked improvement in the condition of the blood. The change is, however, due to other causes. For instance, the checking of the excessive hæmorrhage induces an arrest of the secondary anaemia which accompanies it.

Patients treated for cancer also frequently show an improvement in the blood condition, evidenced by an increase in the number of red cells and a nearly normal colour index. These improvements undoubtedly occur, though they may be only temporary.

Most of the diseases in which there are blood changes have been subjected to radiations in the hope that benefit might accrue. Evidence exists which proves that it is possible to exercise a considerable influence upon a number of these diseases. Leukaemia generally responds for a time at least to radiations, and there is no reason to assume that the improvement is only a variation in the course of the disease. The effects are too marked and exist for too long a period for this to be so.

#### *Technique for Diseases of the Blood and Ductless Glands.*

This will vary with the effects we wish to produce. If a rapid action is required it should be the aim to induce a profound effect upon the blood cells. This can best be done by irradiating large areas of the skin surface with very lightly filtered rays. The first inch of tissues below the skin absorbs about 75 per cent. of the total of these rays, and consequently if the blood-supply is up to the normal the percentage of radiation absorbed will be considerable. When deeper effects are likely to be more helpful than more penetrating radiations may be employed. A filter should be used to absorb a percentage of the softer radiations.

For the irradiation of the spleen and other deep organs filtered rays are employed, the filter in this case being used to protect the skin, which is likely to receive large doses of rays if repeated applications are required.

### THE TREATMENT OF DISEASES OF THE PELVIC ORGANS.

Early in its history the extension of radiation treatment took in the diseases of the uterus, and attention was particularly directed to the enlargement of the uterine arising from fibromyoma. The effect upon these structures was led up to by experimental work carried out in 1905 by Halberstädter, who first noticed atrophic changes in the ovaries of rabbits as a sequel to irradiation by X rays.

Similar observations were made by Bergonié, Tribondeau, and Recamier. Reifferscheid described changes occurring in the human ovary as a sequel to irradiation by X rays. These effects were observed in cases treated by X rays and subsequently operated upon. Many other observers have recorded changes produced in the ovary as a result of prolonged X ray treatment. The majority of the results given are presumably those produced by relatively small doses of X rays, and no details are submitted as to the penetrative quality of the ray or the filtration employed. Albers Schönberg, Henish Bordier, and later Gauss and Lembcke, give results obtained by the more intensive form of treatment, the latter having worked out a very extensive technique, using filtered rays of moderate penetration, and giving results showing improvement as the intensity of the dosage increased.

Later work in America and England on intensive lines has given improvement in results altogether greater than was at one time thought of. The advent of the Coolidge tube and apparatus capable of exciting it adequately have further improved the technique and put within our reach the possibility of administering fairly large doses at a considerable depth from the surface of the body. Further, the introduction of many ports of entry and the angling of the tube to focus the beam of rays upon a given part have rendered it possible to increase greatly the dose at a given spot. The ovary on either side is taken as the landmark upon which the rays should be focussed.

#### *Mode of Action of the Radiation.*

The action of the rays appears to be primarily exercised on the ovary and its blood supply, suppression of function leading to atrophy of the structure and cessation of the menstrual hæmorrhage. The latter is the most troublesome symptom arising from fibromyoma. The improvement in the patient's health may in fact be attributed to the cessation of the hæmorrhage. The atrophy of the ovaries is, however, accompanied in a number of cases by a diminution in the size of the tumour. It is reasonable to assume that an action is exercised on the tumour itself. It is, therefore, advisable when treating the ovarian areas, to include the tumour as well.

The anterior abdominal wall is mapped out into a number of areas. The tube is arranged in treating each area so that the beam of rays may be focussed upon a given spot. If each ovary gets the maximum effect from those "ports of entry" on the side in which it lies, the tumour also receives a very large proportion of the radiations passing through it. A part of these radiations being absorbed by the tumours, changes must therefore occur in its structure as a result of the dosage it receives.

Whatever the action may be and upon whichever structure the rays act most, there is no doubt whatever that in the treatment of those conditions many marked beneficial results can be obtained by carefully applied courses of radiations. It will therefore be necessary to describe in some detail the technique now employed, the type of case likely to benefit, and to analyse the results obtained.

#### *Technique for the Treatment of Fibromyoma of the Uterus and Other Conditions of the Pelvic Organs.*

The technique, although chiefly employed for the treatment of fibromyoma, may be also applicable to such conditions as tumours of the other pelvic organs, the ovary, malignant disease of the pelvic organs, and in the prophylactic treatment of cases of new growth after removal. It is also applicable in a modified form for the treatment of conditions such as endometritis, fibrosis of the uterus, and for the production of sterility in conditions requiring such treatment.

With a modern installation the Coolidge tube offers advantages over any other tube in use. By using a high tension transformer with the tube a uniform series of exposures can be readily and rapidly carried through. The heating current is adjusted to give the desired penetration and the whole series of irradiations can be administered under precisely the same conditions. The dose should be measured by the Sabouraud and Noiré pastille, or by a photographic paper, or by any method which is known to be reliable.

A filter of at least 3 mm. of aluminium is used, and it should be placed, if possible, midway between the tube and the patient's skin. The secondary filter, consisting of chamol leather, several layers of thick paper, and loofah sponge enclosed in a linen bag for convenience, is placed upon the skin under the tube box. The time taken to produce the tint B varies with each installation, and the current it is capable of passing through the tube. An average of about five minutes to each dose can easily be obtained, using 2-3 ma. in the coil circuit. If the current is increased the time will be shortened proportionately to the amount of the increase in the intensity. A "hard" ray is necessary. Between 8 and 9 on the Bauer qualimeter is a useful radiation to employ in these pelvic conditions.

The anterior abdominal wall is marked out into a predetermined number of areas, the landmarks used being the level of the umbilicus and the pubic arch. As many as 2 ports of entry can be utilised in this way. In addition, the areas may be extended into the lateral wall of the abdomen.

and the posterior aspect. These extra areas are useful when it is necessary to get in a very large dose quickly in acute cases. Each area receives the same dose of radiations.

#### *The Question of Dosage.*

It is advisable to commence the treatment just after the cessation of the menstrual period in cases where that is possible. The whole of the areas may be treated at one seance where it is necessary to do so, but from experience it has been found that it is better to divide the dose into two or three days. This diminishes the exhausting action on the patient arising from the continuous treatment of one or two hours or more, and lessens the after-effects upon the patient.

The aim of treatment is to produce the result gradually, so it is necessary to give three or more seances before the patient is really benefited. It is quite possible to produce a result in one or at the most two seances, but the effect on the patient is often very injurious for a time, as serious reaction may be induced when the very intensive line of treatment is adopted. As a rule, in the average case a satisfactory result may be looked for in from 3 to 6 seances, each consisting of 10 to 12 areas. It is not at all uncommon for the period after the first seance to be more excessive than those before the treatment, so it is necessary to caution the patient on this point if she is not to be discouraged and discontinue the treatment.

The improvement is gradual, beginning, as a rule, after the second series of treatment. The menstruation or hæmorrhage generally ceases after the third series and may not be seen again. It is, however, advisable to administer one or two further series in order to keep up the action.

#### *Immediate and Later Effects.*

There are certain conditions produced by the treatment of which the practitioner should be cognisant if he is to be in a position to advise his patients on these and other points of importance arising in the course of treatment. Of these the most important is the so-called reaction induced by the effects of the radiation. These may be divided into (a) immediate effects, (b) later effects (reaction, &c.).

Of the *immediate effects* nausea is most common. This is probably due to the inhalation of highly ionised air which is invariably found in the vicinity of high-tension electrical machinery and possibly to the generation of ozone in the vicinity of the active X ray tube. Headache is often met with and is attributable to the same causes. Giddiness is a common symptom and may be directly traced to change of posture, most patients suffering temporarily and briefly from this when they arise from the X ray couch. Patients frequently go to sleep while being treated. This is possibly due to the monotonous hum of the active electrical apparatus.

The remedy for most of these conditions is simple. For faintness a small dose of sal volatile will suffice. Eau-de-Cologne sprinkled on a towel and laid over the patient's face will serve to minimise the effects of the ozone and ionised air. An electrical fan in the near vicinity of the tube will quickly change the air and carry off some of the ionised air. In prolonged treatments a little oxygen in an inhaler will revive the patient.

The *later effects* come on several days after the treatment, and their appearance has a direct relationship to the intensity of the dose. In large doses it comes on earlier, possibly the next day, but in the average not for two or three days. In cases where the dosage has been very heavy intense prostration may follow, with rapid pulse, raised temperature, and feelings of malaise. The temperature may rise to 103° and 104° and remain at this limit for some time, when patients may become extremely ill. The treatment consists of rest in bed and careful attention to diet. Medicinal treatment should be used as the symptoms indicate.

The patient generally recovers in time for the next series of treatment, which is due, as a rule, in about a month from the preceding one. Generally a degree of tolerance to the treatment develops and the patient shows hardly any reaction to subsequent doses, but a number of patients never acquire this tolerance and dread the repetition of the treatment on account of the distressing symptoms it produces. In these cases it is probable that the dosage has been too great for the patient's general resistance. The after-effects may in these cases be minimised by giving the treatment at longer intervals, or giving smaller doses and carrying the total amount over a longer period.

#### *Type of Case likely to Benefit from X Ray Treatment.*

Although it may be assumed that tissue changes may be induced in practically any form of pelvic disease, and that in a number of these the action will be beneficial, yet for practical guidance it is necessary to survey carefully the field of usefulness and indicate where radiation treatment is likely to give better results than other methods such as the operative, where it is likely to help towards a cure when combined with the operative and other forms of treatment, and particularly to indicate when it is wise to hold one's hand and decide against X ray treatment. This involves a résumé of the conditions met with, particularly in the present instance with regard to fibro-myoma.

While it has been admitted that up to the present the interstitial fibroid is the most suitable for radiation treatment, several writers have pointed out that practically all forms of fibroid respond favourably. The small tumour is more likely to become amenable to treatment than the very large tumour which fills the pelvis and the greater part of the abdomen. It is also worthy of note that the majority of the patients submitted to X ray treatment have been for one reason or another unsuitable for operation. Hence the results secured in a number of cases have been obtained in patients who were too bad for operation, and therefore presumably not favourable subjects for any form of treatment from the curative point of view.

A typical instance of this is found in the case of a patient who was rapidly sinking from profuse hæmorrhage, and who in the earlier stage of her malady refused to submit to operation. Later, when she was willing to do so her condition was so grave that the surgeon refused to operate. As a last resource she was taken to an X ray department in an ambulance. Treatment was pushed vigorously and in a short time the patient was out of danger. Later she made a complete recovery.

Sir John Phillips in a valuable paper<sup>1</sup> states that he has used X rays in nearly all forms of fibroid with beneficial results.

Any case of fibroid tumour will be benefited by radiation treatment if the symptoms are not urgent enough to call for immediate operation. The need for operation may be determined by: 1. The amount and frequency of the hæmorrhage and the secondary effects upon the patient. 2. The size of the tumour and rate of growth. 3. The pressure effects upon other structures. Even in this class of case radiotherapy may achieve results if the patient is willing to risk the effect of very intensive treatment and any other danger incident to its use.

There are other factors, such as the age of the patient, which may be taken as a guide to the practitioner in these cases. Till recently it has been said that patients under 40 years should not be treated by X rays or radium. More recently it has been found that at any age the patient may be beneficially influenced, and that if modified results are all that are required it is possible to produce them. Instances of this kind will be met with in severe dysmenorrhœa associated with an infantile type of uterus. Such patients should be warned of the probable complete cessation of menstruation if the treatment is pushed to its limit.

There are other conditions than fibroids, such as menorrhagia from any cause and endometritis, which may be influenced by treatment.

Put briefly, the advantages the treatment possesses over other forms are that it is quite painless, and, if it fails, operative measures may be employed under the same conditions as before or even under improved conditions. It is not accompanied by so much risk as the operative, and the after-effects are not so disturbing or lasting. Reaction may, however, in a number of cases be rather disturbing. The final result is brought about gradually and the patient is not so seriously affected by the climacteric symptoms induced in both methods of treatment. It is perhaps obvious that if the patient has the whole matter put clearly before her she may decide upon the radiation method in preference to the operative.

#### THE TREATMENT OF MALIGNANT DISEASE.

The treatment of malignant disease by radiations, as has been shown, is now widely recognised. The indiscriminate use of the method has in the past somewhat detracted from its value. In the earlier days X rays were tried in hopeless

<sup>1</sup> THE LANCET, 1918, i., 427; Archives of Radiology and Electrotherapy, 1918.

cases. Even now we are compelled to resort to their use in cases which we recognise as beyond the reach of any therapeutic agent so far as cure is concerned.

#### *Palliative Treatment.*

This leads us to the consideration of the palliative use of X rays in cases which are quite hopeless. Pain may be relieved, tumours are reduced in size, and the general health of the patient improves. The treatment is palliative in another sense, because it must be recognised that in bad cases of cancer, where it is known that the patient cannot be cured, the mental state of the patient has to be considered. Careful use of X rays in these cases will give an amount of comfort to the patient which is altogether out of proportion to any physical benefit received.

It is pathetic to have to deal with these patients. The hope of benefit, even cure, from, to them, a wonderfully powerful agent, takes possession of them to the end. Patients will struggle to the X ray room when it is obvious to all that they cannot possibly be relieved of their troubles. How far it is justifiable to encourage these patients I leave to the practitioner to decide. It is, however, noticeable that if nothing at all is done to help these victims they soon lose hope, become depressed, and quickly succumb to the malady.

In this relationship it is remarkable how much response may be obtained in extensive superficial carcinoma involving the skin and adjacent structures. I have seen extensive involvement of the skin clear up under practically continuous X ray treatment. By this is meant daily doses to numerous areas of skin. The treatment may be carried on for several weeks in this way.

#### *Possibility of Good Results in Very Grave Cases.*

Cases which are apparently hopeless respond well to the radiations, and a period of good health results. A striking instance of this kind may be quoted.

A man of about 35 had a sarcoma of the right testicle removed by operation. I saw him about two years after the operation. He was nearly in extremis, the abdomen was enormously distended, and there was serious engorgement of the superficial vessels of the anterior abdominal wall. The abdominal cavity was filled by a large mass of new growth, this being nodular and very hard. The legs were oedematous, and, to judge from the physical condition of the patient, treatment seemed as if it would be useless. However, it was thought advisable to attempt to help the man. Large doses of X rays were administered to several areas of the abdomen—back, front, and laterally—the idea being to get in a large dose rapidly. Improvement soon set in, the tumours diminished, and the swelling of the legs subsided slowly, this being aided by regular massage to the limbs.

In about three to four months the patient was able to walk. He attended as an out-patient for over a year, receiving treatment at intervals. It is now over a year since treatment was commenced. The patient is at work and is able to carry on, the condition being quiescent. He remained well for over 18 months, when he returned for further treatment.

The next case, although not one of malignant disease, illustrates the degree of influence which can be exercised over a very large tumour.

A patient attended the Great Northern Central Hospital over eight years ago suffering from an enormously enlarged spleen, the organ reaching down nearly to the pubic arch. He was anæmic and appeared to be rapidly going down hill. He was admitted to the hospital and received doses of radiations three times a week for a month. At the end of that time there was no visible improvement and the question of removal of the spleen was discussed. I asked that a continuation of the treatment should be advised after a short interval. This was done, the spleen steadily reduced in size, and in about a year had returned nearly to the normal. Treatment at intervals of three or four weeks was administered. When last heard of about a year ago the patient was in good health and had been actively engaged in business for about eight years.

These cases are, I admit, exceptionally good from the point of view of treatment. The prognosis in both was as grave as it could be, yet both responded to treatment in a remarkable way. I quote them in support of the treatment of hopeless cases by palliative measures, because we cannot say when a patient will not respond in some measure to the radiations.

In our endeavour to obtain results in these cases we resort to combined treatment by X rays or radium and the injection of salts of metal in a colloidal form. Theoretically the proposition is a sound one, since it is possible to obtain

secondary radiation effects from this method. I am quite of an open mind in regard to the value of colloidal salts of metals. I have seen good results obtained, but, on the other hand, the results obtained by radiations alone are equally good.

I am often asked about the value of potassium and magnesium salts in this connexion. No objection should be raised to their use, since theoretically, if we can saturate the tissues with the salts, the radiation effects may be enhanced. The only proviso I make is that they should be discontinued if the patient's health is affected by their use.

Salvarsan and its substitutes may be used, good results being sometimes seen when it is combined with radiations.

#### *Prophylactic Treatment.*

It is reasonable to assume that if it is possible to bring about the disappearance of a small superficial nodule of new growth by X ray treatment, it should be possible to effect a similar change in structures more deeply situated in the body.

In the first place, after an operation for the removal of a cancerous growth the tissues in an area spreading from the seat of the growth are damaged by the manipulations of the surgeon, and therefore more prone to become infected. Secondly, the fluid from the growth itself may contain cancer cells in an active condition, and these, if squeezed into the tissues along with the lymph, may settle on damaged tissue, and so at a later date give rise to what is known as a "recurrence." Thirdly, the lymphatics spreading out from the region of the tumour may already be infected or deep-seated glands may be involved. It is in the hope of checking the development of one or other of the above complications that we resort to prophylactic treatment.

In view of the above facts it is logically certain that the sooner the treatment is commenced after operation the more probable is it that a beneficial influence will follow. Indeed, several authorities advocate the pre-operative treatment in addition to the post-operative. A number of workers advocate the administration of the first treatment at the operation when the tissues are fully exposed. The only objection to doing so is the time it takes thoroughly to irradiate the whole area of the wound, the lymphatics in the axilla and superclavicular areas and the deep mediastinal glands. If this method is employed the first dose should be confined to the open wound. Later, in a day or so, the patient will be able to submit to further treatment if the apparatus can be brought to the bedside.

In whatever way the treatment is commenced it must be thoroughly administered so as to cover all possible sites of recurrence, and the treatment should be kept up for about one year or longer from the time of the operation. Opinions differ in regard to the frequency of the dosage. Some good results have been seen in patients who have had many weekly doses, followed at a later date by fortnightly treatments. The dose in these instances has to be rather smaller at each séance than in those treated at longer intervals. The technique should be similar to that described for the treatment of uterine diseases.

It may be asked what proof have we that prophylactic treatment does any good at all, and the question is a pertinent one. We can produce no proof that recrudescence is actually prevented, but we know that, in the experience of radiologists, a result of the treatment is that the percentage of superficial recurrence is somewhat smaller in the later years of treatment than it was in the earlier when the technique had not been perfected. Manifestations still appear in the deeper structures—i.e., in the thoracic walls and glands of the neck, axilla, and mediastinum. The time has not yet come when we can make any positive statements on this point. Years may elapse before we can prove by statistics that any good is being done in the way of preventing recrudescence, but in the meantime we can definitely state that radiation treatment helps the patients in other ways. A general tonic action is evident, scar tissue is rendered pliant, the recovery of limb movements is facilitated, and, lastly, the patient is encouraged to help herself and is supported in this effort by the fact that others are endeavouring to help her.

#### *Curative Treatment.*

The last and not the least important of the uses of radiations in dealing with malignant disease brings us to a consideration of the value of these in an attempt at the cure of a particular case. How far have we reached towards this

end? Great care and judgment are necessary in arriving at a decision to rely solely on either X rays or radium for the cure of a new growth.

The first consideration is whether there is any prospect of curing an early case. Undoubtedly a number of cases have been cured by a thorough exposure to X rays or radium. Such cases are naturally early ones where the lesion is superficial, and therefore readily accessible to the radiations. Rodent ulcer can be so dealt with, and superficial epithelioma may also disappear after treatment and remain cured for lengthy periods.

Sarcoma is another condition in which success may be obtained.

One particular case occurs to me in which a recurrent growth on the face was completely cured by a course of radium exposures. The original growth had affected the eyelid. Recurrence had been dealt with on two occasions by operation, as had also the primary manifestation. The glands on the affected side in the cervical region had become involved. The patient was treated eight years ago and, so far as is known, remains healed. When last heard of about a year ago she was quite well.

The final judgment is, however, in favour of operation in all early cases of cancer, because the balance of opinion is against an attempt to cure by radiations when an operation can so easily be performed and a radical excision offers the best chance of cure. Delay in these cases is always dangerous, because it is not yet possible to be certain that radiations will invariably yield a successful result, and surgery may ultimately have to be employed under much less favourable conditions if we fail to bring about a disappearance of the growth by X rays and radium.

AN ACCOUNT OF  
AN INFECTION IN MESOPOTAMIA DUE TO  
A BACILLUS OF THE GAERTNER-  
PARATYPHOID GROUP.

BY WILLIAM MACADAM, M.A., M.D., M.R.C.P. LOND.,  
CAPTAIN, R.A.M.C. (T.C.); BACTERIOLOGIST ATTACHED TO  
— BRITISH STATIONARY HOSPITAL, MESOPOTAMIA  
EXPEDITIONARY FORCE.

(A Report to the Medical Research Committee.)

A SERIES of inagglutinable organisms culturally and morphologically indistinguishable from *Bac. para. B* have been isolated from the blood stream by the writer in Bagdad between July and December, 1918, and it is learned that similar findings have been recorded in a number of cases in other areas of Mesopotamia. In view of the bacteriological results obtained and pathological lesions revealed at autopsy in three fatal cases which occurred, an account of the findings, along with a note on the clinical history of the series of cases, has been deemed worthy of record to draw attention to the possibility of other cases of fever with or without marked pulmonary lesions being due to the same organism, as well as to raise the question of its relationship to the infections of the classical "enterica" group, especially paratyphoid B fever.

Characters of the Organism Isolated from the Blood and from  
the Various Organs.

The several strains of the organism under review all have the cultural and morphological characters of the Gaertner-paratyphoid group. It is most closely related to *Bac. para. B* and, as will be shown, it does not appear to belong to the *Bac. aertrycke* type. Up to the present the organism has been obtained from nine cases, from seven of which it was isolated during routine blood-culture investigation of "P.U.O.'s." In the remaining two cases it was isolated at autopsy from the lungs and spleen, no blood culture having been carried out during life. The organism has so far not been isolated from the urine or stools in spite of numerous examinations, but at one of the autopsies it was obtained in pure culture from the bile.

All the strains give similar microscopic appearances—an actively motile short, stout, Gram-negative bacillus or coccobacillus, with some tendency to pleomorphic formation. The growth on agar is less transparent and oily in appearance than the usual paratyphoid cultures, and is usually more profuse. There is no liquefaction of gelatin. On

MacConkey's medium the colonies are indistinguishable from the paratyphoids. Biochemically the organism produces acid and gas in mannite, glucose, dulcitol, maltose, galactose and arabinose, no change occurring in lactose, saccharose, and inulin. Litmus milk becomes at first slightly acid, changing to alkalinity on the fifth to seventh day; there is no production of indol.

Serological Characters.

On isolation, all the strains were inagglutinable even in low dilutions of the high-titre sera (Lister Institute) for *B. typhosus*, *B. para. A*, *B. para. B*, and *B. enteritidis* (Gaertner). After eight subculturings in broth spread over a fortnight, all the strains had become agglutinable to para. B serum in dilution of 200 and 250; while in the case of four of the strains, each of which was subcultured on 30 occasions, agglutination was obtained in considerably higher serum dilutions. Fine soft flocculi with a distinctly opalescent supernatant fluid were present in dilutions ranging up to 1000 and 2000 (titre of the para. B serum 6000), but marked sedimentation was never present in dilutions higher than 200 or 250. In none of the tests with para. B serum did I obtain the clear supernatant fluid which usually results in similar tests with *Bac. para. B*. Consistently negative results were obtained in the agglutination tests with all other high-titre sera (Dreyer's method slightly modified being the technique adopted).

Specific sera for three of the strains have been obtained by the immunisation of rabbits, a titre of 6000 to 10,000 being reached without any difficulty. All the nine strains were agglutinated to practically the full titre, whereas two stock strains of *Bac. para. B* never showed any signs of clumping in higher dilution than 1 in 250. For example, strain No. 6, which was obtained in pure culture from the lungs at autopsy by plating the lung juice on MacConkey's medium (as also from the heart blood and spleen), was agglutinated immediately after isolation by the rabbit immune sera for the strains No. 3 and 4 in dilutions of 8000 and 10,000 respectively, while para. B. sera (Lister Institute, titre 6000) failed to produce any reaction with this strain in dilution 1 in 50. "Zones of inhibition" were occasionally met with in the agglutination experiments both with the specific para. B serum, as well as with the sera obtained from the immunised rabbits, but no reference need be made to them in the present connexion.

It has unfortunately not been possible to obtain from England subcultures of recognised *B. aertrycke* strains, but through the kindness of Lieutenant-Colonel Ledingham, R.A.M.C., I was enabled to compare the reactions of a strain of presumed *Bac. aertrycke* isolated from an epizootic among guinea pigs by Major Glöster, I.M.S., at Amara. The behaviour of this bacillus with the sera produced from the immunised rabbits was very different from that of all the nine strains of the organism under review. Agglutination with sedimentation was present up to the 250 dilution, while the same indeterminate type of clumping associated with the fine soft flocculi as was obtained with the stock *B. para. B* was present up to a dilution of 1 in 1000. Nor did this *B. aertrycke* strain become more agglutinable after repeated subculturings, while it may be noted that it clumped with the Lister para. B serum practically up to titre. Thus it appears improbable that the series of organisms under investigation belong to the *B. aertrycke* group, although the evidence is meantime incomplete in the absence of experiments with specific *B. aertrycke* sera.

Agglutination of organism with patient's serum.—One case—No. 1—is of special interest, in that it was possible to

Dilutions of Serum of Case No. 1.

	25	50	100	200	250	500
No. 1 ... ..	++	++	++	±	±	—
No. 2 ... ..	+	+	±	±	±	—
No. 3 ... ..	++	++	±	±	±	—

No. 5 ... ..	++	+	+	—	—	—
Stock <i>B. para. B</i> ...	+	+	—	—	—	—
Stock <i>B. para. A</i> ...	+	—	—	—	—	—
Stock <i>B. typhosus</i> ...	+	+	—	—	—	—

carry out agglutination tests with two lots of this man's serum against his own organism as well as against the others of the series. Unfortunately no serum was obtained before the twenty-fourth day of illness. On this occasion the

serum gave negative results. On Oct. 28th, 1918—i.e., the forty-second day from the onset of No. 1's illness—blood was again obtained, and the following results were obtained in macroscopic agglutination tests with the serum against five of the strains and against our stock T.A.B. emulsions. This patient has been inoculated with T.A.B. vaccine in November, 1916, and again in February, 1918.

**Absorption tests.**—Although it was not to be expected that much information was to be gained from absorption tests when the Para. B agglutinogens of all the strains of the organism are relatively slight in character and produce such atypical flocculi as compared with those of the homologous organism, yet a number of such tests have been carried out. Out of six experiments with Strain No. 4 immune serum the following result was recorded in two instances:—

Strain No. 4 rabbit immune serum (titre 6000). Titre before and after absorption with (A) *Bac. para. B* and with (B) Strain No. 3:—

	(A)		(B)	
	Original titre.	After absorption	Original titre.	After absorption.
<i>B. para. B</i> ... ..	250	<50	250	<50
Strain No. 4 ... ..	6000	6000	6000	500
Strain No. 3 ... ..	6000	5000	6000	> 500 <1000

It is seen that *Bac. para. B* removed all the para. B co-agglutinins from the rabbit immune serum, but did not touch the agglutinins for the homologous or similar organism, whereas after absorption with a presumably similar bacillus (Strain No. 3) more than five-sixths of the agglutinins for the homologous organism were removed, as also were all the para. B co-agglutinins. In the other four tests such removal of the para. B co-agglutinins, by the strain presumably similar to the homologous organism, did not occur. This may have been due to the use of an insufficiency of organisms in the saturation of the serum, although from the extent of the removal of the homologous agglutinins this does not appear probable. The atypical character of the flocculi present in the ordinary agglutination tests and the incompleteness of the reaction, as shown by the persistent opalescence in the supernatant fluid, may throw some light on the inconstant results obtained, and further investigation in this direction is required.

In four experiments in which para. B. high-titre serum was saturated with strains No. 1 and 4 there was no absorption of the agglutinins for those organisms or for the homologous organism *B. para. B*. It is very probable, therefore, that we are dealing with a specific organism the serological characters of which are quite distinct from those of *B. para. B*.

#### Pathogenicity to Animals.

No special experiments to test pathogenicity have been carried out owing to the small number of experimental animals available. Some observations were made, however, during the course of preparation of immune sera in rabbits. One animal, which had previously received two intravenous injections of 225 and 900 million of dead bacilli, was found dead on the third morning after an intravenous dose of 500 million living organisms; while another rabbit died after 300 million live bacilli following on three doses of 300, 1200, and 3000 millions respectively of killed organisms, all given intravenously.

Post-mortem examination showed that both animals had died of a hæmorrhagic septicæmia. Petechial hæmorrhages were present on the pleural surfaces, as well as in the substance of the lungs. Some were larger than petechiæ, and in the case of the second rabbit one extensive hæmorrhage involved a third of the right lower lobe. Small hæmorrhages were present in both spleen and kidneys.

The intestinal tract also showed lesions of considerable interest. Discrete hæmorrhagic areas ranging in size from a pinhead to a millet seed were to be seen in the lower part of the duodenum, while in the jejunum and ileum they were well marked over a length of three inches, and extending in less degree for nine inches below. There was some associated œdema of the mucous membrane, but there was no naked-eye involvement of the lower part of the ileum or of the appendix. The great intestine appeared normal.

#### The Clinical Aspects of the Infection with Some Notes on the Morbid Anatomy.

The clinical history, &c., along with the post-mortem findings in the three fatal cases, is as follows:—

**CASE 3.**—Pte. W., aged 30, was admitted to hospital at Bagdad on Sept. 16th, 1918, with a fever, the temperature curve being suggestive of malaria, and the clinical symptoms of "influenza," of which there was an epidemic in Bagdad at the time. The man had been transferred from a convalescent camp, having been invalided from Persia for debility following clinical malaria. No malaria parasites had been found previous to admission, nor were any detected during several examinations while the patient was in hospital. After five days' intermittent temperature (98° to 104°) (see Chart 1) there appeared definite signs of a right

CHART 1.

basal pneumonia, spleen being palpable on deep inspiration. Condition became very critical and six days later patient died. There was no paratyphoid eruption. Leucocyte count on day before death 12,000 per c.mm.

**Autopsy** (10 hours after death). Lungs: Right middle and lower lobes in state of grey hepatization. Upper lobe acute congestion. Left lung normal. Pleura: Right cavity contains 8 ounces clear serous fluid with a recent exudate of lymph over the affected lobes. Heart: Signs of dilatation. Myocardium soft and friable. Spleen: Twice the normal size, soft and diffident. No pigment deposit to be seen by the naked eye or in smears. No malarial parasites detected. Intestines: Peyer's patches apparently perfectly healthy. Nothing abnormal seen in any part of the alimentary canal.

**Bacteriology.**—Cultures from the spleen and consolidated lung made direct on to MacConkey's medium gave a pure culture of the cocco-bacillus described above. This organism was agglutinated by its homologous serum obtained from an immunised rabbit in 1 in 6000 dilution. Originally inagglutinable to all the specific sera, after numerous subcultures, it reacted with para. B serum (titre 6000) as follows: Dilution 1 in 1000 +; 1 in 2000 ±.

**CASE 4.**—Sgt. G., aged 40, had been 12 days in hospital suffering from vague nervous symptoms, having suffered from shell shock in France in 1915, from which he had never completely recovered. Patient appeared to be doing well during his 12 days' residence, when his temperature suddenly shot up to 102° (Chart 2) and there developed symptoms of bronchitis and rhinitis. On the third day of fever signs of a right apical pneumonia developed. Five days later the right lower lobe and also the left apex showed signs of involvement. No suggestive rose spots were seen. Restlessness and delirium latterly became a marked feature, the patient dying on the fifteenth day of illness.

**Autopsy** (14 hours after death).—Emaciation slight with moderate hypostatic lividity. Pleura: Right sac contains 8 oz. blood-stained fluid. No adhesions or lymph exudation. Left sac normal. Lungs: Consolidation of greater part of right lung—viz., whole of lower lobe, middle lobe, and posterior portion of upper lobe. In section the colour was yellowish grey, the consistence distinctly friable, with a suggestion of softening, while there was a purulent exudate on squeezing the consolidated areas. Left lung healthy except for marked congestion, especially of upper lobe.

Heart: Showed dilatation of the left ventricle with a large antemortem clot in the corresponding auricle. Myocardium pale, flabby, and easily friable. Spleen: Slightly enlarged, softish. Stomach and intestines (great and small): Normal in appearance except for a pink oedematous condition of the jejunum and upper part of the ileum. This may have been associated with the presence of several ascarides in the small intestine. Kidneys: Marked cloudy swelling with some fatty changes.

Bacteriology.—Three blood examinations for malaria during life were all negative. Blood culture on the ninth day of illness gave a pure culture of a Gram-negative coccobacillus with the characters above described, while at autopsy the same organism was obtained from spleen, lung, and contents of gall-bladder. Although originally inagglutinable, all four strains after a week's subculturing were agglutinated by para. B serum in 1:2000 dilution, tests with the other specific sera being negative. The serum of the animal immunised with this strain easily reached a titre of 10,000. Smears from the sputum during life, as well as from the lung juice at autopsy, showed some Gram-positive cocci in addition to numerous Gram-negative bacilli, but no organism morphologically resembling the pneumococcus was seen.

CHART 2.

CASE 6.—Pte. D., aged 32, admitted to hospital on Nov. 20th, 1918, as suffering from anæmia, thought to be due to bleeding hæmorrhoids, gave a recent history of diarrhoea and colicky pains for the preceding 12 days. History of intermittent bleeding from the bowel during the previous two months was elicited, blood with clots being passed along with formed stool, while the occasional occurrence of prolapse on defæcation was reported. Four days after admission patient developed a condition which was diagnosed as acute bacillary dysentery. Fever asserted itself so that the patient's temperature reached 102° (Chart 3), while 4-6 non-fæculent motions were passed daily consisting chiefly of bright red blood associated with blood clots and a little mucus in the form of sago-like granules. Their appearance was altogether much more suggestive of intestinal hæmorrhage than of the usual acute dysenteric "B. and M." stool. On microscopical examination the cytology did not suggest bacillary dysentery, very few cellular elements being present apart from blood cells. No entamoebæ were seen while on cultivation on MacConkey's medium on three occasions, no non-lactose fermenters were in evidence. Blood films failed to reveal the presence of any malarial parasites. The blood picture did not suggest a primary blood disease. The only striking feature was the pallor and distortion of the red cells, but no megalocytes or nucleated red cells were seen.

At first the sigmoid felt definitely thickened and was acutely tender, but after several days this feature completely disappeared. The patient's general condition suggested marked toxæmia. He was treated with antidyenteric serum, but no improvement ensued. On Nov. 28th—i.e., the twenty-first day of fever—severe watery diarrhoea set in, the stools being pea-soup like with flecks of blood. On Dec. 4th the temperature fell, collapse set in, patient falling into a comatose condition, and death took place on Dec. 6th.

Autopsy (performed 20 hours after death).—Body considerably emaciated; blood watery. Respiratory system normal. Cardio-vascular system: Pericardium normal; dilatation of right ventricle. Myocardium pale and fatty

Nothing else of note. Alimentary tract: Stomach: Small erosions in the mucosa. Lower part of duodenum and upper part of jejunum—mucous membrane oedematous with signs of acute congestion. Scattered petechial hæmorrhages but no erosions. Ileum normal. Large intestine: Congestion of transverse and descending colon with numerous small

CHART 3.

erosions and hæmorrhages in the mucosa. No marked ulceration and no thickening present. Liver and kidneys: Marked cloudy swelling with fatty changes. Spleen: Normal in size, soft and diffuent. Suprarenals and thyroid normal. Red marrow of sternum and ribs—no marked hyperplasia.

Bacteriology.—A bacillus with the morphology and cultural characters of the other organisms of the present series was obtained in pure culture from the spleen and heart blood. In the first agglutination tests with this organism after isolation the findings were: Against immune serum of strain 4, ++ in 5000, + in 10,000. Against Lister Institute para. B serum (titre 6000), nil in 50.

Summary of Chief Symptoms.

As for the cases in general, some of the clinical data have been tabulated in Table A, while a summary of the notes on the chief symptoms observed is given below. No special stress can be laid on any clinical feature which may not occur in the course of enteric group infections, although the prominence of respiratory symptoms has been somewhat striking in the present series of cases.

Course of the fever.—The fever, which was in most instances of sudden onset, appears to be of variable duration, depending partly on the relative severity of the infection, partly on the extent of involvement of the respiratory tract. The milder cases lasted 5-7 days on the average. Two patients (Nos. 1 and 7) each ran an 11-days' fever, at first intermittent and latterly of the continued type (see Chart 4). Of the fatal cases one of the pneumonias (No. 4) ran a continued fever during the whole 15 days' illness. The other (No. 3) showed a markedly intermittent course for ten days, becoming of the continued high type on the onset of extensive lung consolidation four days before death. The fatal "hæmorrhagic" case (No. 6) ran a 28-days' pyrexia, and was of the continued type during the 14 days he was under observation.

As regards relapses, none occurred while the patients were convalescing in hospital or subsequent to discharge, as far as could be learned from their after history.

Respiratory system.—Marked involvement of the respiratory tract was a feature of all the cases except three. Thus in four instances in which this inagglutinable paratyphoid-like organism was obtained by blood culture, the infections were of a mild character and of short duration, while bronchial catarrh was so prominent a feature that all four cases had been labelled "bronchitis" or "influenza with bronchitis." As already described, two of the fatal infections appeared clinically to be suffering from lobar pneumonia, as was subsequently proved at autopsy (Cases 3 and 4). Of the three cases with no respiratory symptoms two of them had been considered enteric infections, while the third was

regarded as a markedly toxic type of bacillary dysentery. Smears and cultures of throat swabs from a number of the patients gave nothing of pathogenic importance.

CHART 4.

**Alimentary system.**—Gastric and intestinal symptoms were in most instances inconspicuous. Vomiting, except in case No. 6, was absent, while constipation was the rule. Case No. 5, considered clinically an "enterica" infection, suffered from diarrhoea in the early period of the illness, while in the fatal "pneumonias" (Nos. 3 and 4) there was no lesion of the intestinal tract except that one showed a pink cedematous condition of the jejunum and upper part of the ileum. The Peyer's patches and solitary glands appeared quite normal.

albuminuria was present in the cases examined. The presence of pus cells or other cellular elements was not observed.

#### Discussion.

The question as to whether this bacillus found associated with the present series of cases is an aberrant type of *Bac. paratyphosus B* or whether it is an undescribed organism (which for convenience may be called *Bac. paratyphosus C*) belonging to the Gaertner-paratyphoid group is a matter for discussion. The fact that, after as many as 30 subculturings, none of the strains of the organisms are agglutinated by specific para. B serum (Lister Institute) in any dilution at all approaching its maximum titre is important, especially when it is remembered that the isolation of readily agglutinable para. B bacilli during the course of routine blood-culture work in Bagdad has been far from uncommon. Consideration must also be taken of the unusual nature of such agglutination as was obtainable with high-titre para. B serum—viz., the very fine soft flocculi which seldom produced much sedimentation and which never left a clear supernatant fluid. Nor do the serological observations, described above, point to the organism having closer affinities to the *Bac. aertrycke* group, although it has to be noted that unfortunately it has not yet been possible to obtain from Europe any of the recognised high-titre *B. aertrycke* sera.

Clinically, although it is well recognised that marked respiratory symptoms may be a common accompaniment of paratyphoid B infections and, indeed, have been the chief feature of certain enteric epidemics, yet the local microbic infection in these cases is still a matter of dispute. Bacilli of the Gaertner-paratyphoid group have been reported on various occasions as having been isolated from the sputa, but as to whether they were originally present or were merely secondary invaders does not appear to have been conclusively settled. It has not been possible to consult the literature on the subject, hut Miller,<sup>1</sup> in his recent Goulstonian lectures (1917) on Paratyphoid Infections, says:—

"The paratyphoid bacilli apparently do not attack the lungs and pleura themselves. Lahhé, however, mentions

TABLE A.—Statement of Clinical Data.

No.	Clinical diagnosis of case.	Duration of fever.	Day of disease of positive blood culture.	Isolation of organism from other sources.	Probable place of infection.	Character of infection.
1	Bronchitis (N.Y.D. enteric group).	11 days.	9th day.	—	Bagdad.	A somewhat severe attack, the course suggesting an enteric infection.
2	Influenza with bronchitis.	6 "	3rd "	—	"	A short but, very acute fever.
3	"Clinical malaria" followed by lobar pneumonia.	14 "	No culture made.	Lungs, spleen, heart blood.	Kermanshab.	Both very severe and fatal infections with all the signs of lobar pneumonia.*
4	Bronchitis followed by lobar pneumonia.	15 "	9th day.	Lungs, spleen, bile.	Bagdad.	
5	Bronchitis.	7 "	4th "	—	Kifri.	A mild infection.
6	Acute dysentery (bacillary?).	28 "(?)	No culture made.	Spleen, heart blood.	Tekrit.	A very severe toxic infection, with a hæmorrhagic colitis ending fatally.†
7	Bronchitis (N.Y.D. enteric group).	11 "	9th day.	—	Bagdad.	Nothing of special note. Clinically very suspicious of an enteric infection.
8	Bronchitis.	5 "	4th "	—	"	Both mild short fevers.
9	"	7 "	4th "	—	"	

\* See p.m. notes.

† See detailed notes on clinical history and autopsy.

The third fatal case (No. 6), however, showed distinct intestinal lesions, which have been described above. This patient had complained of marked hypogastric tenderness in the early days of his fever. Otherwise abdominal distension or tenderness was not a feature of the cases.

**Nervous system.**—There was no nervous symptom of special note. Delirium was present towards the end in the two fatal cases of pneumonia, while No. 6 sank into the typhoid state before death.

**Skin.**—Nothing suggestive of rose spots or of an eruption of any kind was seen in any of the series.

**Abdominal organs.**—**Spleen.**—Its size varied considerably in the different cases. Some of the notes report the organ as being slightly or distinctly palpable on deep inspiration. In one fatal case it was two fingers-breadth below the costal margin, while at the other two autopsies the organ showed nothing of special note. Malarial parasites or pigment was not seen in any smears of the splenic pulp. Liver, kidneys, and bladder: Nothing of special note. The usual febrile

a case of abscess of the lung from the pus of which *B. para. B* was isolated. Apart from this rather special case, I cannot find a recorded instance of paratyphoid bacilli being found in the pleural fluid ante mortem nor in the lungs post mortem. I can only think that if these organisms do attack the lungs and pleura it must be but rarely.

In the two cases of the present series which showed extensive pneumonic consolidation the organism was isolated from the lung juice in pure culture on MacConkey's hile medium, while, except for a few scattered diplococci which did not resemble the pneumococcus, it alone was seen in stained lung smears.

The duration of the bacillæmia is so far undetermined, as positive blood cultures were obtained from the third to the ninth days inclusive in the various cases. Marked involvement of the intestinal tract, except where the infection assumed the character of a hæmorrhagic septicæmia, was uncommon, and the absence of any lesion of Peyer's patches,

<sup>1</sup> Miller: THE LANCET 1917, i., 831.

or of the solitary glands, may be of importance as a differential feature.

My attention has recently been drawn to an account by Neukirch<sup>2</sup> of an epidemic which occurred between March, 1915, and the early part of 1917 in Anatolia and Turkey from the cases of which an organism called *Bac. Erzindjan* was isolated. This organism, the author concludes, is closely related culturally to *Bac. para. B* and the *supestifer* group, but it can be differentiated by serological tests. From the title of his paper Neukirch is inclined to identify the organism with the Glässer-Voldagsen group, placing his reliance on the agglutination test. Yet he states that all the strains of *Bac. Erzindjan*—like those isolated from the present series of cases—produced acid at first in litmus milk, followed later by alkali production, except one which showed no initial acidity. On the other hand, all the Glässer-Voldagsen strains tested produced acidity and remained acid until the end of the ten days recorded. It seems difficult to accept the serological similarity and ignore this constant biochemical difference between the organism under review and the Glässer-Voldagsen group. The cultural characters of *Bac. Erzindjan* cannot be compared with our *Bac. para. C*, as Neukirch has so far described its action on glucose and lactose only.

This worker distinguishes two main clinical groups of cases from which the *Bac. Erzindjan* was obtained in pure culture: (1) the "typho-septic" type, with a mortality of 46 per cent.; (2) the dysenteric type, with a much smaller mortality of 6·7 per cent. For comparison he quotes a 5 per cent. mortality rate as having occurred among the infections of the "enterica" group. Two other groups are also mentioned—viz., four cases of slight general infection and a solitary case of pyelonephritis. Neukirch draws special attention to the very variable clinical picture met with, and to the difficulties of distinguishing these cases from those of typhoid, paratyphoid, and dysentery, apart from a bacteriological diagnosis. I have not had access to the original article to ascertain what types of infection are included in the group called "typho-septic," but it appears very probable that the causative organism in the present series of cases of infection among British troops is the same as that described as *Bac. Erzindjan*.

Most of the cases which are the subject of this paper appear to have been infected in the Bagdad area, although in three instances the evidence available pointed to the place of infection being much farther up the line—viz., at such widely separated places as Kermanshah, Tekrit, and Kifri. For the present it is impossible to say anything about the epidemiology. The probable prevalence of the infection among the native population requires investigation, while it would be of considerable interest to learn whether a similar para. C-like organism has been among the bacteriological findings in Palestine and in other areas of military operations in the Near East.

#### Summary.

1. A series of inagglutinable organisms culturally and morphologically indistinguishable from *Bac. para. B* have been isolated by blood culture in Bagdad during the latter half of 1918, and it is learned that similar findings have been reported in other areas of Mesopotamia.

2. Of the three patients suffering from the infection who died, two of them were clinically regarded as cases of lobar pneumonia. At autopsy the same cocco-bacillus was isolated from the lungs and spleen, and in one instance from the gall-bladder also. Respiratory symptoms were a prominent feature of most of the cases, while the symptomatology and course of the fever were usually not suggestive of an enteric group infection.

3. Serologically all the strains on isolation were inagglutinable to the "enterica" high-titre sera (Lister Institute). After 30 subculturings of the organism agglutination of an atypical character was present in dilutions up to 1 in 1000 of specific para. B. serum (Lister), while in comparison a 1 in 10,000 dilution of the same serum led to marked clumping with two stock strains of *B. para. B*. Absorption tests tended to confirm those serological differences. The sera obtained from three rabbits immunised with different strains of the bacillus readily agglutinated the whole series of organisms in dilutions of 1 in 5000 to 1 in 10,000; whereas no reaction resulted with the stock *Bac. para. B* in dilutions

higher than 1 in 250. Equivocal findings were also recorded in tests with a strain of presumed *Bac. aertrycke*.

4. The real identity of the organism is so far undecided. In its behaviour with specific sera it is distinguishable from both *Bac. para. B* and *Bac. aertrycke*, although closely related to both. It has been learned with interest that an epidemic in Turkey and Anatolia has been described as due to a paratyphoid-like organism with similarly atypical serological characters. If the bacillus should eventually be proved not to be a specific organism but to be simply a variety of *Bac. para. B*, the practical importance of its recognition seems to lie in the fact that the recognised high-titre para. B sera fail altogether to agglutinate it on isolation, and after numerous subculturings they react with it, to only a limited extent, while a special immune serum is necessary for its ready identification. Many of the organisms which have been from time to time reported as non-agglutinable or "temporarily inagglutinable" para. B bacilli may belong to this para. C-like group.

It is with pleasure that I acknowledge my indebtedness to Lieutenant-Colonel J. C. G. Ledingham, C.M.G., R.A.M.C., consultant bacteriologist to the Mesopotamian Expeditionary Force, for his great assistance and helpful criticism; while I desire to express my thanks to Lieutenant-Colonel H. J. Crossley, R.A.M.C., O.C. — Stationary Hospital, Bagdad, for access to and the use of the clinical records of the described cases.

Bagdad, January, 1919.

## SOME OBSERVATIONS BEARING UPON THE COMMOTIONAL FACTOR IN THE ÆTIOLOGY OF SHELL SHOCK.

By ALFRED CARVER, M.D. CAMB.,

LATE CAPTAIN, R.A.M.C. (T.C.); DIRECTOR OF THE BIRMINGHAM  
PSYCHONEUROSIS CLINIC.

IN THE LANCET of Jan. 11th, 1919, Dr. C. S. Myers raises three important questions relating to the problem of "shell shock." The first is as to "the existence of distinct commotional and emotional syndromes." I believe that the following experiments, carried out with the assistance of Lieutenant A. Dinsley, R.A.O.C., prior to the appearance of Dr. Myers's article, will prove of interest as bearing upon this point. The conditions under which "shell shock" arises in man render accurate observations so difficult that experiments upon animals seemed advisable carried out so that the weight of explosive used could be kept constant, its nature and composition known but varied at will, and the actual distance of the animals from the centre of detonation measured.

#### Effects of High Explosives.

When a high explosive is detonated there arises first a sudden terrific blow which exerts a compressing and shattering force upon its surroundings in every direction. This is instantaneous and is followed immediately by an equally sudden decompression, thirdly rapid oscillatory or vibrating movements are set up, which die down only gradually. Each of the three results requires analysis when considering the effects upon living organisms. A further effect is the purely demoralising effect produced by the vibrations outside the sphere within which any demonstrable physical destruction or injuries occur. Evidence will be adduced to show that the Germans arranged their shell-fillings so as to enhance this peculiar effect. This, fully in keeping with other of their methods, might be described as "frightfulness by detonation."

If a high explosive be detonated at a point X three zones may roughly be mapped out around it, their radii depending, amongst other things, upon the weight of explosive.

Zone A is delimited by the extent of obvious gross disruption, and may be termed "the zone of brisance"; within it a crater is formed, barbed wire and other obstacles are blown aside, broken and distorted; animals are killed and usually lacerated; other high explosives immediately detonated.

Outside this is a second zone, B, which may be termed the "zone of decompression," for the disturbances within it seem mainly attributable to this factor, though coarse shaking movements also play their part. In zone B the

<sup>2</sup> Neukirch, 1918, Ztschr. f. Hyg. u. Infektionskrankh. lxxxv., 103.

gross effects of shattering and disruption are no longer evident; animals placed in it and protected from flying fragments rarely show external signs of injury; only sensitive explosives, whose tonal standard is somewhat similar to that of the primary explosive, detonate.

Beyond this can be named a zone, C, in which the effects of detonation are modified further. The effects upon animals in zone C vary considerably, but as a rule a short transitory state of stupor is followed by a stage of excitement.

#### *Experiments on Fish.*

Experiments were first carried out in water, the test animals being fish (perch); a depth charge of 6 oz. of gelignite was used.

Fish in zone A became obviously "hors de combat," showed gross lacerations, and were sometimes torn in pieces.

Fish in zone B after the detonation floated in an almost vertical position, but slightly inclined with their ventral surfaces uppermost, their mouths just protruding above the surface. At this early stage the whole of their bodies were rigid, and if the fish were pushed down to a depth of about two feet they sank slowly to the bottom of the tank and there remained. The earliest sign of animation was violent and irregular spasmodic movement of the opercula and gills. The first reflex which could be elicited from such fish was erection of the dorsal fin upon stimulation of the skin to either side of it. At the end of about half an hour those fish which eventually recovered began to swim when the abdomen was stroked with a piece of stick, but these first swimming movements carried the fish only forward in a straight line, and no turns were made even when an obstruction was met. The movements were made with the ventral surface uppermost and almost flush with the surface of the water. At this stage, then, the fish had lost their power of equilibration, and with this the whole of their orientation in life.

The majority of those which attained the stage of swimming in this way gradually became more active, and eventually, after passing through a side-uppermost posture, began to swim about in a natural manner. In about 12 hours after the detonation all those fish which had not succumbed were, to all appearances, completely normal.

Dissection of the dead one showed definite congestion of the foreparts of the brain, hæmorrhagic points in the mid-brain and basal ganglionic region, and generally hæmorrhage in the upper region of the spinal cord and medulla. The gills and other viscera, also the muscles attached to the vertebral column, frequently showed areas of hæmorrhage. Dissection of perch taken at random immediately after the detonation either revealed varying degrees of the above-described changes or else, at macroscopic examination, nothing abnormal was discovered.

Towards the outer margin of B zone and the inner region of C zone the effects upon fish could not be sharply differentiated, the severity of the symptoms and the anatomical findings gradually diminishing with the distance of the creature from X.

Fish well out in C zone dashed about vigorously in a disturbed and excited manner, but though their movements were wild and apparently haphazard they generally made away from X. A few came to the surface and splashed about, but when netted no physical abnormality could be demonstrated, and those returned to the water soon behaved in a completely normal manner.

In considering the effect upon fish of vibrations set up in water one should bear in mind the great development in these creatures of special sense organs directly susceptible to stimulation from such. It is conceivable that the effects of the violent vibrations just described are in part due to excessive stimulation of these special sense organs. If this be so, the shock, though still physical, might be more accurately described as of neurogenic than of commotional origin. It is well known that in man unconsciousness can be produced by purely reflex stimulation, the whole ego being swamped by an excessive flood of afferent impulses which gives rise to a condition of neurogenic shock; there being no "commotio." As I have no evidence which leads me to think that neurogenic shock of this type plays any appreciable rôle in the production of the war neurosis I shall not refer to this aspect of the subject any further.

#### *Experiments on Mammals.*

Experiments with mammals (rats and mice) were carried out on land. Perforated zinc cages were used, partly to fix

the position of the animals and partly to protect them from flying fragments. These cages were distributed at measured distances around X. The charge was standardised to 3 oz. of explosive.

In zone A cages in and immediately outside the crater formation were simply blown away and distorted, the animals being killed or severely wounded by direct violence; their eyes were bloodshot, and there was often external hæmorrhage from the ear, nose, or mouth. On dissection the alveoli of the lungs were found to be ruptured, and to a variable extent the central nervous system and other viscera showed hæmorrhagic areas. With the effect in A zone we are not further concerned; the changes would seem to be due to the direct blow of displaced air, which strikes like a solid substance, and to the effect of the exceedingly rapid decompression succeeding this.

Along the inner part of zone B the findings, though similar to the above, were much less in degree. Animals were invariably rendered unconscious irrespective of the extent or nature of the lesions demonstrable, and occasionally were found to be dead, even though no external injury was present; upon dissection the only abnormal finding, to coarse examination, was general capillary engorgement, especially noticeable in the central nervous system and meninges. Whether this indicates that vaso-motor changes play any part in the associated phenomena I am not prepared to say.

Further out in zone B a state of stupor or transitory loss of consciousness, of much shorter duration than in zone A animals, was an almost constant result. During the stage of recovery twitching movements of the limbs were often present, and then the animals, if stimulated by appropriate physical agents, showed massive and exaggerated reflex reactions. For example, the application of a pin-prick to one hinder extremity might be followed either by bilateral contraction of the hinder extremities or even by a generalised convulsion. There was frequently considerable difference in the activity of the reflexes on the two sides of the body—a hemiplegic distribution—but, as a rule, the fore-limbs were more severely affected than the hind and showed weakness and dragging after the latter had recovered normal movements. Reflex responses, though vigorous, died away quickly, but were often succeeded by a weaker repetition even when no fresh stimulus was given. Rapid fatigue of the response on repeated stimulation was a noticeable feature. By dissection no gross macroscopical evidence of internal injury to such animals was revealed, but capillary engorgement, as in animals nearer X, was generally demonstrable.

Animals left alone after this stage had been reached gradually began to behave in a more normal manner, though for a considerable time their conduct, postures, and gaits were awkward. The severity of these disorders varied greatly from animal to animal, which rendered it impossible to delimitate, from biological observations, the precise boundaries of the several zones. Speaking generally, the effect diminished gradually in proportion to the distance of the animal from X.

For some distance beyond what I have termed the C zone, animals crouched down and huddled themselves together whenever a detonation took place; after this state of diminished activity a state of apparent excitement with increased restlessness was the rule. Animals left exposed in this position during a series of experiments invariably crouched down as flat as possible and seemed to be in an absolutely stuporose condition. When liberated they made no effort to run away but remained for a long time in a huddled-up posture. The interpretation of these latter peculiarities of behaviour is difficult. Should fear be allowed as the cause or are other more material factors also at work?

If instead of employing a single explosive at X one detonated a composite charge all the above phenomena became more pronounced, but the increased effect was particularly noticeable in zone C and its immediate surroundings.

#### *Observations on Soldiers.*

In this connexion it is of interest to record some observations carried out upon physically and mentally fit men of an "Ammunition Proof and Demolition Section" during the ordinary course of their duties. The staff, drawn from infantry-men with some technical knowledge, was sheltered in a well-protected dug-out about 100 yards from X, the

centre of detonation. In this case X was a large crater formed in the centre of the demolition ground, and contained the official maximum weight for each single destruction—viz., 200 lb.

Although the men had some technical knowledge they did not know the nature of the explosive fillings which were to be destroyed on any given occasion, and it was interesting to study the differing effects of these upon them. Simple single fillings, such as T.N.T., picric acid, and tetryl, rarely caused any of the men discomfort under the conditions described, yet when mixtures such as ammonal (British), amatol (British and German), donarit and glückauf (German) were detonated many of the men complained of unpleasant sensations—e.g., “catching in the throat,” “peculiar feelings in the chest,” “creepy feelings down the spine,” or “weakness of the legs”; others were seen to shake violently and the rate of their pulse and respiration increased.

When separated or layered fillings of different explosives having widely differing velocities of detonation were demolished the effects became greater and several of the men passed into a stuporose condition, followed in some instances by violent shaking and twitching, and in one case by vomiting.

Men thus affected were not fit for duty for the next two or three days, and even then, although fully aware that no real danger attended the demolitions, they seemed to be in a state of mental anxiety and were more readily affected by detonations than previously.

#### *Effects of Detonations of Shells with Layered Fillings.*

Examination of German shells shows that in certain of them layered fillings were deliberately employed, although involving more time and labour. Captured German documents reveal the fact that this type of shell was intended for use immediately prior to an attack, and in sectors where the opposing troops were well entrenched. Hence we must infer that the Germans were aware of the peculiar demoralising effects which attend the detonation of these mixed and layered fillings.

Most of those who have been through a severe German bombardment bear witness to the demoralising effect it had upon them, and state how this was succeeded, owing to summation of effect as the bombardment continued, by a sort of “fixed glassy feeling” even when the shell did not detonate particularly close to them. In order to eliminate as far as possible, if not entirely, the psychic factor which in such cases plays its part it is instructive to study cases in which the detonation fell like a “bolt from the blue” upon individuals who were not in a state of tense expectation or fatigue at the moment of the incident.

At the same time one cannot ignore the importance of the predisposing factors, which are highly complex. There is, however, nothing distinctive about them as regards the type of neurosis developed. So far as my observations go the most important of them—viz., fatigue both physical and mental—seem to operate in a general way by lowering the resistance of the individual to all forms of shock, though naturally the individual of poor make-up is more profoundly affected than the robust type.

#### *Commotion from “Direct Concussion.”*

First to deal with the syndrome in cases where commotion resulting from “direct concussion” without wounding, as in animals exposed in the B zone, is the primary causal factor.

The initial symptom is unconsciousness, often of several hours’ duration and possibly persisting for days. Consciousness when first recovered does not remain clear, but the patient passes through a stage of variable duration during which he loses and regains it—the so-called “dipping of consciousness.” Some degree of aphasia and sphincter troubles are common at this stage, which is frequently associated with an active delirium in which the patient re-enacts episodes of his military service.

At this time the general condition is one of extreme exhaustion; all mental operations are sluggish and there is great difficulty of concentration. Amnesia both for immediate and remote past is a common occurrence. The voice is often altered, becoming slow, monotonous, and higher pitched than normally. In severe cases these symptoms tend to persist for many months and relapses are easily induced by any form of fatigue.

Clinically the importance of recognising these symptoms is that the prognosis in such cases is much graver than in those giving an exaggerated account of events after they had been thrown down or partially buried. In cases exhibiting the above symptoms prolonged rest, with freedom from strain of all sorts, is essential. Psycho-therapeutic treatment is of little avail except in so far as fixation of symptoms may have occurred in the later stages.

#### *“Indirect Concussion.”*

Cases of “indirect concussion” corresponding to animals on the borders of the B and C zones demand more careful discrimination. The history is complicated by the fact that there is a tendency on the part of the patient to exaggerate, but careful questioning will overcome this difficulty.

Unconsciousness or stupor of comparatively brief duration is the rule, and the phenomenon of “dipping of consciousness” is not observed. Active delirium is rare, and is not of the occupational type. Amnesia though frequently present is only retrograde, is less extensive, and more readily recovered than in the type of case previously described.

The severity of the symptoms, as well as their duration, is also less, but there is a greater tendency to the superimposition of functional troubles such as paralyses and algeias; these may supervene immediately but, more commonly, they develop later in the course of the disease when the symptoms of commotional origin are recovering. If they are removed by appropriate treatment the patient, after a few weeks’ complete rest, generally feels as well as ever. Easy fatigability and diminished power to concentrate the attention are apt to be more persistent symptoms, and although the patient declares himself “quite fit,” it is advisable to insist upon a more prolonged period of rest.

#### *“The Last Straw.”*

Cases in which the neurosis arose as the result of exposure to shell fire in what I have referred to as the C zone are naturally much more difficult to differentiate from those of purely psychogenic origin, and it cannot be said that they are recognisable by a distinctive syndrome. The description already given of men so exposed in the “Ammunition Proof and Demolition Ground” affords a better picture of the onset of the neurosis than can be got from an analysis of the more complicated conditions arising during trench warfare.

In a rather disparaging way any shell detonating outside the A zone is commonly referred to as merely “the last straw,” its influence being thus tacitly attributed to purely emotional factors. It is, nevertheless, a last straw which cannot be lightly disregarded, and one is justified in maintaining that a sufficient number of such “straws” will cause the downfall even of the most robust.

It should be remembered that the stability of any explosive is under these conditions diminished, and its sensitiveness so raised that it may eventually detonate. There is no difficulty, then, in conceiving that physical processes, which cause alterations in the direction of *instability* in a relatively simple chemical compound such as an explosive, may, in a similar way, affect the far more delicate colloidal solutions contained in the central nervous system.

#### *Combination of Physical and Emotional Causes.*

With cases of purely psychogenic origin, many of whom never reach the danger zone, it is not my purpose to deal. The syndrome closely resembles that with which we are familiar in civil life, though the “current conflict” is usually of a different nature. Psychological analysis reveals the repression and the conflict which is being shirked.

The point which seems to have been universally overlooked is that under the conditions of modern warfare the soldier is constantly subjected both to physical and emotional causes of shock, and that the two factors operate in conjunction. Also whichever factor be in any given case the primary one the individual, once sensitised by either, remains for a long time, perhaps always, hypersensitive to both forms of stimulation, and a vicious circle is thus established.

Although one not infrequently meets with cases in which apparently a single factor has been operative, a careful study of histories in the special military neurological hospitals has led me to conclude that the combined action of the two aetiological factors is much the more common event. If this be so, it is not surprising that those who expect to find either definite commotional or emotional syndromes in the bulk of their patients are generally disappointed.

*Conclusion.*

I have tried with the aid of the experiments, here briefly set forth, to give a picture of the early syndrome which distinguishes the more severe cases of commotional shock, but as the experiments themselves no less than clinical experience indicates, the symptoms in slighter cases become almost inextricably blended with others which appear identical with those resulting from emotional shock. Hence, though at the two extremes one may with ease deduce the nature of the primary pathogenic factor from a study of the syndrome exhibited, this becomes increasingly difficult as one approaches the intermediate members of the series, and one's judgment is largely determined by the aspect from which one approaches the problem.

## INTRACRANIAL LESIONS:

## THREE INTERESTING CASES.

By R. ECCLES SMITH, M.B. LEEDS, F.R.C.S. EDIN.,  
SURGEON TO THE SURGICAL HOSPITAL, BARRY, WALES.

THESE cases, each differing widely from one another, but each having in common a hemiplegia, are recorded together, the first on account of its rarity, the second for its interesting obscurity and want of a true diagnosis, and the third merely as a reminder of what one must be prepared for as an aftermath of the war.

*Cavernous Sinus; Thrombosis; Hemiplegia; Pyorrhœa Alveolaris.*

Patient, a man, aged 28, was admitted to hospital on March 7th, 1918; long history of pyorrhœa alveolaris. On Feb. 20th seven teeth were extracted from right upper and lower jaws. He developed an alveolar abscess in the right lower jaw with cervical suppuration, requiring incision. On Feb. 27th temperature  $104^{\circ}$ ; repeated rigors and symptoms of septicæmia. The chest was involved in an early bronchopneumonia of a septic type. Loss of power on left side of body.

On admission patient was extremely ill. His mouth was foul. There was marked necrosis of the lower jaw all along the right alveolar margin, with sloughing of the gums. Both antra were apparently not involved when searched by transillumination. The right lung showed signs of bronchopneumonia, with some pleural effusion; sputum full of streptococci; blood culture sterile. Intense proptosis of right eye, with œdema of lids; marked chemosis and paralysis of sixth nerve. The fundi were normal except for tortuosity and enlargement of retinal veins on right side. There was a little œdema over right mastoid region due to back-pressure in the petrosal sinuses. He was quite conscious, but was almost completely paralysed in face, arm, and leg on left side. Reflexes abolished; no sensory changes; incontinence of urine and feces.

Intravenous eusol 1 per cent. was given daily for seven days; initial dose 100 c.cm., rapidly increasing to 250 c.cm. Temperature of septic type,  $103.5^{\circ}$ – $104^{\circ}$ ; respirations, 30–35; pulse, 120–130. After the second injection of eusol the symptoms improved. On the third day the proptosis was a little less; sixth nerve began to recover. On the fourth day the paralysis of the arm was not so complete; on fifth day improvement in leg. The paralysis was never absent, but improved until he could partly move arm and leg. By the seventh day the sphincters were normal. The proptosis decreased up to a certain point and signs of chronic back-pressure began to show in the veins of the lids and in a solid unaltering œdema of the conjunctiva. The right fundus remained as first noted. The chest lesion began to dominate the scene on March 14th; increasing respirations and gradual deterioration; duct parotitis which did not suppurate. By March 16th he was profoundly toxicemic; death on March 23rd from septic broncho-pneumonia and septicæmia.

The points of interest are: 1. The infection and thrombosis of the cavernous sinus by septic absorption from pyorrhœa alveolaris via the pterygoid plexus of veins, through the ophthalmic veins into the sinus. 2. The hemiplegia due to pressure by direct swelling of, or added tissue œdema about, the sinus, on that part of the right crus cerebri containing the motor fibres of the face, arm, and leg of the left side, where it is in relationship with the cavernous sinus. And of the sixth nerve as it lies intimately related to the outer wall of the sinus. 3. The improvement in the hemiplegia and squint and proptosis suggesting organisation of the

clot and absorption of surrounding œdema and establishment of collateral circulation. 4. Recovery might possibly have been hoped for had not septicæmia and bronchopneumonia led on to death.

*1 Case for Diagnosis; Cerebral Decompression; Recovery.*

Patient, a man, aged 43, apparently perfectly healthy, and walking in the street, suddenly gave an articulate cry and fell down in a fit. Syphilis 20 years ago; teetotaler 13 years. On admission to hospital on August 8th, 4 P.M., he presented a further fit. Twitching and fine tremors started in the left hand, passing up the arm, involving face on left side, and ending in left lower extremity; great distress. His tongue was bitten before a gag could be obtained. Pupils dilated and fixed; eyes turned to the left. Consciousness during jactitations and intervals. Reflexes were absent on left side; Babinski's sign negative. Total flaccid paralysis of the left side of face, arm, and leg. No alteration of sensation. Urine normal except for a slight trace of albumin. Distinct œdema of discs, especially on right side. Pulse 120, full, and bounding. B.P.: systolic 130 mm., diastolic 100 mm. Lumbar puncture, fluid under pressure; 20 c.cm. clear fluid withdrawn.

At 8 P.M. patient was deeply comatose and cyanosed, respirations slow, and breathing stertorous. Pulse-rate had fallen to 56, full, and thudding. Pupils equal, semi-dilated, and reacting slightly, and fully dilated in a fit. Complete paralysis as above, but with total loss of all reflexes, including sphincters. Every few minutes patient, although unconscious, was thrown into most violent left-sided jactitation, beginning in face and ending in lower extremity, and lasting 30 to 40 seconds. No external injury was present.

Having diagnosed compression due to a pathological rather than a traumatic lesion with a localising site in the right cerebral hemisphere, I advised decompression. In cerebro-spinal fluid only an excess of small lymphocytes; cells of any kind scanty. This is of extreme importance in later developments.

Operation was carried out at 10 P.M. under chloroform. A large semilunar flap was turned down on right side of skull over motor area and middle meningeal artery. The brain was exposed over area of 2 square inches, including precentral gyrus. No extradural hæmorrhage; middle meningeal artery intact. A normal dura mater bulged; loss of brain pulsation. No subdural hæmorrhage observed, so whole of dura in decompression area was turned down. The brain bulged out rapidly, assuming size of duck's egg; meninges apparently normal; no œdema or suggestion of thrombosis. The skin and fascial flap was then sutured completely. Breathing and pulse-rate immediately improved and he was returned to ward.

On August 9th in the morning there was complete recovery of consciousness and ability to talk. Paralysis remained and reflexes absent; no sensory changes. On the 10th conversation sensible. Partial recovery of lower limb; face and arm paralysed; control of sphincters. On the 11th further recovery of leg with sluggish knee-jerk, arm could be moved, no fine movements possible. On the 12th Wassermann reported strongly positive. On the 13th power in arm and leg increased; facial paralysis almost stationary. Coördination was defective. Steady improvement continued, even in the face, until August 18th.

On the 18th he suddenly had a coarse tremor of the left arm, lasting a few seconds, repeated several times daily; over 25 tremors recorded in a week; otherwise patient is making a good recovery. On the 28th sudden return of violent jactitations affecting arm and then leg, but not face; 24 violent fits in 12 hours. No loss of consciousness in convulsions. Brain at site of decompression very tense and enlarged. Lumbar puncture removed 40 c.cm. of clear fluid under great pressure; fluid similar to last. Complete paralysis of leg and arm followed and lasted two days before return of slight movement in the leg. During this time slight athetoid movements continued in the arm and leg.

From August 30th no further tremors; steady return of power, chiefly to leg, continued. The reflexes were now exaggerated on that side; Babinski's sign negative. On Sept. 20th he could walk with some spasticity of the left leg; arm be raised with difficulty and hand placed on head; grip good. The eyelids could close; lower supply of facial nerve not recovered; fundi completely recovered. Antiseptic treatment with iodides has been steadily carried out as far as the stomach will allow.

From this point up to his discharge on Oct. 27th a change was seen in his mental attitude, which had been quite rational. He has been emotional and childish and a little verbose; general health good; able to carry on light work in civil life. He was last seen in February, 1919 (seven months after admission). The mental attitude remained the same; slight improvement in gait and arm power. Tremor of tongue and slight tremor of hands had appeared.

*Points of Interest and Discussion.*

A man with a strong positive Wassermann is brought in with a left-sided hemiplegia, left-sided Jacksonian epilepsy, and cerebral compression. Where and what is the lesion?

A. At the time of onset of the symptoms the strongest feature was increasing intracranial compression with coincident hemiplegia on the left side, denoting hæmorrhage in the region of the basal ganglia from the lenticulo-striate branch of the middle cerebral artery. This would not account for the localised and definite convulsions which essentially belong to a cortical lesion, the two conditions remain uncorrelated.

B. Syphilitic thrombosis of the cortical vessels over the right motor area, with a syphilitic meningitis, might explain both the palsy and the epilepsy. But it does not explain the excessive intracranial pressure leading to profound coma, nor does the normal condition of the meninges and vessels found allow of such a theory.

C. Hæmorrhage into a cyst or a softened gumma in the region of the basal ganglia can only explain the hemiplegia and compression, but not the cortical symptoms. The recurrence of convulsions 21 days after decompression, relieved by lumbar puncture, tends to strengthen the view of further hæmorrhage into such cyst.

D. The abundance of small lymphocytes in the spinal fluid in the early stage, with the onset of changes in the mental attitude later, strongly suggest early general paralysis of the insane which, as is well known, may be ushered in by convulsions and even transient hemiplegia. But this fails to supply the explanation of severe compression sufficient to have been fatal without surgical interference.

My own opinion now is that a combination of (C) and (D) is the only means of correlating the antagonistic symptoms.

A photograph showed the site of decompression and protruded brain on the right side, unfortunately almost obscured by his hair. The position of the leg is voluntary. The arm will be noticed to be still lacking power, and the facial muscles are not controlled.

*Latent Meningitis Following Gunshot Wound of the Skull.*

Patient, aged 34, sustained in November, 1916, a severe wound by shrapnel of left frontal bone above air sinus. Both tables were carried away, leaving a semilunar opening in the bone  $2\frac{1}{2}$  inches long by  $\frac{1}{2}$  inch wide. Laceration of frontal lobe. From the injury up to Feb. 1st, 1919, he had recurring headaches with from time to time vertigo. The fundi did not denote any intracranial pressure.

On Feb. 1st, 1919, he was admitted to hospital, having suddenly had four very severe generalised fits with cyanosis and vomiting; semi-coma between convulsions. He was unconscious to his surroundings on arrival. The fits had no localising features, but were very violent generalised clonic convulsions. In the period of quiet a violent fit could be elicited by firm pressure on the scar. Fundi normal. All reflexes present, but sluggish. The scar was very thick, and firmly adherent all round hiatus in bone. The tissues about the scar were slightly œdematous, simulating the puffy tumour of Pott. The convulsions continued frequent and violent. The diagnosis acute spreading œdema of the meninges was made, and operative measures advised.

*Operation.*—Under chloroform the old scar was rapidly excised and site of fracture exposed, well in front of motor area. The hiatus in the frontal bone was filled up with dense scar tissue, consisting of brain tissue, organised blood clot, and the remains of the meninges. The whole was markedly œdematous; cerebro-spinal fluid more abundant than usual. A trephine disc was removed from the sound bone just behind the fracture and the tissues adherent to the ragged bone carefully separated until the brain and meninges were free from the skull. Bone was then removed until a decompression over 2 inches square had been effected. The organised clot and scar tissue were carefully excised from the frontal lobe, hot saline freely used, and the wound closed except for drainage.

On recovery from the anæsthetic two hours later patient had a violent convulsion, followed by a state of acute cerebral irritation, which was continuous and had to be controlled by chloroform anæsthesia. This stage in about ten hours gave place to intervals of lethargy alternating with violent fits. Twenty-four hours later compression symptoms came on and patient developed hemiplegia of the whole of the right side. Coma and death ensued 48 hours after admission.

*Post mortem.*—The frontal lobe on the left side showed marked destruction of old standing, with a dry cavity in the deeper portion suggesting the site of an old abscess which had undergone absorption. On the left side of the brain there was a marked basal meningitis. The meninges were in a state of acute œdema, especially marked on the left side.

No undue localising pressure was noted on the left motor area to account for the increasing paralysis on the right side.

This case illustrates the guarded prognosis necessary in war wounds of the skull. In brief, the majority of such wounds are fatal on the field. Those brought under the surgeon's care either remain clean and recover or become septic and die within a fortnight from suppurative leptomeningitis or encephalitis or end with a hernia cerebri, which remains a menace for all time. This man had apparently completely recovered, with no hernia cerebri or bulging of the brain tissue. Yet over two years elapsed before the latent infection flashed up, ending fatally in an acute generalised œdema of the meninges and a definite localised basal meningitis.

Plymouth.

**COLECTOMY.**

BY JAMES TAYLOR, F.R.C.S. EDIN.,

MAJOR, R.A.M.C.; DISTRICT CONSULTING SURGEON, ALDERSHOT COMMAND.

At present the question of intestinal stasis is much before the profession. The medical journals constantly refer to it, and even the public press has articles on this subject. We are recognising more and more that a great many ailments have their origin in the intestine. In many cases diseases are the direct mechanical result of the delayed passage of food, but much more suffering, and a much greater variety of sickness, is produced by toxins from fermentive processes among the accumulated intestinal contents. Other diseases are produced by germs directly attacking organs after their resistance has been lowered by intestinal toxæmia. The mechanical and fermentive processes are always more or less associated. They act and react on one another, but sometimes one and sometimes the other is the dominant factor in the production of any particular disease.

The treatment of intestinal stasis rests with the physician, but a fairly large proportion of cases get beyond his control and can only be relieved by surgical measures. Many cases only reach this stage because all treatment has been neglected until serious mechanical obstructions and marked toxic changes have taken place.

The most striking results of surgical treatment are seen in the toxæmic cases. Nothing is more impressive than to see a large thyroid shrivel to normal dimensions, or a Bright's disease entirely clear up after removal of the colon. Six years ago after performing an ileo-sigmoidostomy on a woman with inveterate constipation the feeling of well-being which followed was surprising. Within 24 hours she felt entirely different, and the change was obvious to the observer. Before the operation the odour of her breath made it unpleasant to be near her, in spite of the utmost care of her mouth by the nurses. Within a day from the operation this had entirely disappeared, and her muddy complexion became clear incredibly soon. The removal of a controlling appendix or the division of a controlling band will often produce remarkable improvement, but the results which impress one most occur after the more radical operations, and one sees the most wonderful recoveries after the removal of the large bowel.

*Illustrative Cases.*

In this paper I propose to describe some cases in which the changes in the colon itself, resulting from stasis, were such as to demand its removal. They illustrate the effect of the irritating contents on the bowel.

CASE 1.—The colon was not actually diseased, but, being overloaded, had sunk down till almost all the ascending, transverse, and descending portions were in the pelvis. The patient, aged 30, came under my care suffering from severe indigestion. Constant pain and vomiting after food; bowels always constipated. The symptoms were those of gastric ulcer; physical examination confirmed this. When the abdomen was opened an old healed ulcer was found at the pylorus; obstruction not very great. The colon was as described, and obviously was the essential cause of the trouble. The large bowel from cæcum to lower part of pelvic colon was removed, and the end of the ileum joined to the end of the divided sigmoid.

CASE 2.—A boy, aged 18, complaining of abdominal pain for three months. Pain in spasms; during spasms a considerable swelling appeared in right side of abdomen, just

below umbilicus. It was movable and tympanitic, and only slightly tender. At times it would disappear altogether, and the pain would pass off. He was constipated; occasional attacks of vomiting; slight distension of whole abdomen. A diagnosis of chronic obstruction was made, and I thought he had probably a tuberculous cæcum. When the abdomen was opened the end of the ileum was dilated to the size of a normal stomach; walls greatly hypertrophied. In cæcum and beginning of ascending colon was a firm elastic swelling resembling chronic intussusception. The dilated end of the ileum and the whole colon round to its pelvic portion were excised, and an end-to-end anastomosis between ileum and sigmoid made. On examination of the specimen the lumen of the cæcum and lower ascending colon was so narrowed that a finger passed with difficulty. The subserous and submucous coats were greatly thickened and the mucous membrane was thrown into folds, which gave the appearance of a large-celled honeycomb. Professor S. G. Shattock very kindly examined the specimen and pronounced it to be a case of colitis polyposa.

CASE 3.—Six years before coming under my care patient suffered from constipation; appendix removed; condition did not alter during next four years. Then pain began on right side of abdomen; blood in stools. A few weeks later diarrhoea began to be troublesome; much blood and mucus passed. He was in hospital at various times during the next two years, once for five months. When I saw him first he had been under treatment for six weeks without improvement, and I was asked by the physician to perform a cæcostomy. Diarrhoea was constant, as many as 12 motions a day; patient extremely thin and weak. The cæcum was opened and irrigation started. He improved up to a point, but relapsed when cæcostomy opening was allowed to close. More radical treatment was decided upon. The whole colon down to within a few inches of the rectum was excised. The patient stood the operation well, and gradually improved. A certain amount of diarrhoea still resulted from diseased condition of rectum. Cultures were made from the stools, and a streptococcal vaccine was given; this with protargol injections hastened recovery. He was discharged from the Service fit for light employment.

CASE 4.—Patient, a woman aged 53; intestinal obstruction for ten days. There had been much abdominal pain, occasional vomiting, and repeated enemata had only resulted in a very little flatus being passed. The abdomen was enormously distended and somewhat tender. On laparotomy there was an escape of free gas from the peritoneal cavity; free fluid was present in pelvis. The large and small intestines were greatly distended, and a malignant growth was found in middle of pelvic colon. Several stercoral ulcers in cæcum; one had perforated. The cæcum was brought out of the wound, perforation closed, and a Paul's tube tied into the most healthy part. A large rubber drain was then passed down to the bottom of the pelvis, to be left in for several days.

The patient was very ill for about a week; distended bowel very slowly recovered tone, and expelled its contents. After three weeks the abdomen was quite flat; bowels moving freely through artificial anus. Under stovaine and ether anaesthesia an incision was made round the cæcostomy opening, two narrow flaps of skin turned up and stitched together face to face so as temporarily to close the opening. The field of operation was then again thoroughly cleansed, and the abdominal cavity freely opened. The whole colon, except a few inches of pelvic portion, was resected, with about 4 ft. of lower ileum hopelessly matted together as a result of the perforative peritonitis. An end-to-end anastomosis was made, and a tube passed up through the rectum to a little above the line of intestinal suture. Most excellent recovery; healing by first intention.

Eighteen months afterwards the patient is in better health than she has enjoyed for years, the bowels move easily twice a day, and she can lead a normal active life, including horse-riding. There is no evidence of recurrence.

CASE 5.—This is a similar case, a malignant growth in the same situation causing acute obstruction, which had to be relieved in the same way with colectomy a fortnight later. No perforation; only about 8 in. of small intestine sacrificed. Recovery excellent, but it is too soon to say whether any recurrence is going to take place.

CASE 6.—A patient had had a transverse colectomy for gunshot wound of pelvis involving rectum. When the rectum had healed the colectomy opening had to be closed. So much of the transverse colon was damaged that it was going to be difficult to bring the ends together after removal of injured portion. The ascending and descending colon were removed as well and an end-to-end anastomosis made between the ileum and the pelvic colon. Recovery excellent.

These six cases are the only complete colectomies I have had the opportunity of performing. I was surprised at the way the patients stood the operation, especially in the two cases in which so much delay was caused by the precautions to

avoid contamination of the wound from the colectomy opening. The rapid improvement in general health was also striking. I have seen four of these cases recently and, except the case with the ulcerative condition of the rectum, there was no trouble with diarrhoea, the bowels only moving about twice a day. One hears that these patients are always troubled with looseness of the bowels, but that has not been my experience. Even the patient who lost 4 ft. of ileum as well as the whole colon has had no trouble of this kind. Yet another patient in whom I removed about the same length of intestine—8 ft. of small intestine, cæcum, and ascending colon—has suffered from troublesome diarrhoea since. This seems to indicate loss of small intestine as more likely to cause frequent motions than loss of colon.

Sir Arbuthnot Lane is most emphatic that in cases of obstruction from a growth in the colon the whole large bowel, including the tumour, should be removed at the primary operation. The tube which is then passed up through the rectum into the end of the ileum drains the small intestine directly and at once. It seems the ideal method, but I think could only be done by a surgeon of his skill and experience. In my two cases I felt that the patients would not stand more than I did at the first operation, and I also anticipated having great trouble in making my anastomosis tight when the ileum was so much distended. On the other hand, I almost lost my first patient from toxic absorption from the colon, for it took nearly a week to empty itself through the colectomy opening, and the difficulty of doing the radical operation afterwards was greatly increased by the presence of a faecal fistula.

#### *Partial Operations.*

Attempts to relieve patients by partial operations are not very successful. Two recent cases bear this out, and are rather instructive.

CASE A.—I saw this patient, aged 38, in consultation in the country. She had been an invalid for many years, much troubled with indigestion, and not able to do more than move about quietly in her garden. Thirty-six hours before I saw her she was seized with sudden severe abdominal pain and vomiting. When seen by her doctor there was no marked tenderness or rigidity, but enemata failed to produce any result; nothing had passed by bowel since onset of pain. I found the abdomen much distended and somewhat tender in its lower part. Pulse weak but not rapid. Immediate laparotomy was decided on. The abdomen was opened in the middle line and a large gangrenous cæcum presented in the wound. Examination showed extreme visceropexy, and a volvulus of an extremely mobile cæcum had taken place. This portion of bowel was greyish black in colour, had lost its lustre, and rupture seemed imminent. I first incised the cæcum and cleared out the contents; the torsion was then easily uncoiled. I had to remove the colon round to the middle of its transverse portion before a moderately healthy part was reached. I was much in doubt as to whether I should resect the whole large bowel, but decided it was better not to have any raw surfaces on the left side of the abdomen, as the peritoneum was somewhat infected from the gangrenous gut. An end-to-end junction was made therefore between the ileum and the transverse colon. Patient made a good recovery, but she has not put on any more weight, and does not seem to have improved in general health, as I should have expected had the ileum been drained directly into the pelvic colon.

CASE B.—This is a very instructive case, the notes on which Sir Arbuthnot Lane has very kindly allowed me to publish. The patient, aged 36, had suffered from constipation for many years, and about four years before she came to me began to have considerable abdominal discomfort. She was supposed to have appendicitis and had this organ removed; it was noticed that the colon was badly prolapsed. She was no better after this treatment and three months later laparotomy was performed by another surgeon, and the cæcum, ascending and beginning of the transverse colon resected. She was fairly comfortable for the next 18 months, when constipation again became very troublesome, and after various kinds of medical treatment, the abdomen was opened for the third time. Some adhesions were separated, and a loop of small intestine, which had been acutely bent on itself, was sutured to the abdominal wall. She nearly died of ileus, and such was her suffering during the next month that operation was decided on again. On this occasion a lateral anastomosis between the ileum and pelvic colon was performed, and the patient was told that when she had recovered sufficiently the segregated loop would be removed. However, at the end of another year the operator refused to do this, as adhesions had made the operation too difficult.

At this stage I saw her for the first time. She was leading a miserable existence. Large doses of aperients were necessary every day, and often enemata as well. She was in almost constant pain. At times a distended loop of bowel could be seen standing out with waves of peristalsis passing along it. Opaque meal examination showed very marked delay in the small intestine. Most of the contents passed slowly through the ileo-sigmoidostomy opening, but a small quantity travelled through the side-to-side anastomosis made between the end of the ileum and the end of the transverse colon. By this means it reached the splenic flexure, and was held up here for about 48 hours. Although she was taking aperients, it was not till the fourth day that the opaque meal reached the rectum. A barium enema showed a very long and distended pelvic colon, and the fluid could not be forced beyond the splenic flexure. It was obvious that she was suffering from chronic obstruction, which might become acute at any moment. As a radical operation was going to be extremely difficult, I advised her to have it done by Sir Arbuthnot Lane, and I had the privilege of assisting him with it. After carefully separating the adhesions, the very long pelvic colon was divided near its lower end. The bowel was freed and removed from below, upwards, until the ileum above the higher anastomosis was reached. An end-to-end anastomosis between the ileum and the pelvic colon was then made.

The patient had a much happier convalescence after this operation than after any of her previous ones, and her pain was entirely relieved. She is now steadily recovering her strength. Had a complete colectomy been done in the first instance she would have been saved much suffering and four years of invalidism.

#### Conclusion.

Although my experience of colectomies has been somewhat limited, I feel it is worth while publishing notes on the few cases done because there is a very general belief that many patients do not recover from the operation, and that those who do are no longer capable of leading an active life. Operation deaths do occur, but usually because the patient is suffering from a serious organic lesion, and an operation is being done that one may give him the only chance of recovery. One must expect misfortunes sometimes when patients with serious kidney disease are submitted to operation, but the fact that my first six cases of colectomy were recoveries seems to show that the risk is not very great when no very vital organ is seriously involved.

I feel assured that improving the drainage system produces wonderful results, and often efficient drainage cannot be obtained without removal of the large bowel. One sees the effect of improved drainage in those patients with peptic ulcer who have had a gastro-enterostomy performed, and their ileal control freed. The complexion clears, the tongue becomes clean, and the excretion of foul-smelling toxins by the sweat glands no longer takes place, and yet in these cases only slight relief has been given to the obstructed alimentary tract. I feel sure that the great improvement in health often following appendicectomy is not due to the removal of a diseased organ, but to the excision of an appendix which has been controlling the end of the ileum.

## ANEURYSM OF THE HEART WITHOUT SYMPTOMS.

By CLAUDE WILSON, M.D. EDIN.

ANEURYSMAL dilatation of the cardiac wall is rare, though, perhaps, not so rare as supposed, for in many cases of sudden death from heart failure no autopsy is made. The condition cannot be diagnosed during life, and in very few cases has it ever been suspected. It has been found as a solitary lesion in an otherwise healthy heart, but is commonly associated with widespread changes—syphilitic, sclerotic, or fatty. The immediate cause is probably in all cases the blocking of a branch of the coronary artery, leading to atrophy of a limited area of the heart wall.

Occasional cases have been published in the medical literature of many nations. In English there are two well-known monographs on the subject: by Dr. Wickham Legg<sup>1</sup> and Dr. D. G. Hall.<sup>2</sup> In neither of these is the clinical history

dealt with very fully; but it may be stated generally that in the great majority of cases the usual signs and symptoms of cardiac enfeeblement have been present, while angina is a fairly common symptom. But in a certain proportion of cases the severer symptoms of cardiac weakness have been singularly wanting, and I have traced one case, recorded by Dr. F. M. Hughes<sup>3</sup>—in addition to my own—in which there were no symptoms at all.

The patient, a dock labourer who had never had any cardiac symptoms, had worked hard all his life, and had several times been passed as fit for work by doctors. He had had no occasion for medical treatment of any kind during the last 15 years of his life; he walked six miles to his work two days before his death, and was able to continue his arduous labours after his first slight feelings of distress, until on the third day he suddenly dropped dead at the age of 49. At the autopsy the pericardium was found full of blood clot, and in the anterior wall of the left ventricle—near the apex—was an aneurysm the size of a walnut, which had ruptured. The valves and aorta were healthy, but the microscope showed degeneration of the myocardium in the area of the aneurysm and fatty degeneration of the whole heart wall. The other organs were healthy, and there was no evidence of syphilis.

#### Account of a Case.

The case under my care is not less remarkable.

The patient, aged 60, was married at 36; three children, all grown up. Pale complexion which made her look somewhat fragile, but with a wonderful record of health; could not remember ever having been ill. Cheerful disposition. Very active worker at home and abroad. Good walker: could take a 20-mile walk, and go up the hills as fast as her daughters. This record ceased on Sunday morning, Sept. 8th, 1918, when after breakfast, for the first time in her life, she felt somewhat sick. However, she went to church—a mile walk, mostly uphill—and ate the usual substantial meal on her return. At 2 P.M. some visitors turned up. She entertained them, but was glad when they departed at 3.30 as she then felt sick and ill and said she would go to bed. At 3.45 I received a message from her husband asking me to see her at once, and I went at once.

I found her sitting up in bed, complaining of a pain behind the sternum, and of nausea. Almost immediately she was violently sick and vomited her undigested meal. She then said she felt better and laid down, but the nausea continued and she still felt some pain. Her pulse was regular—about 75—and the heart sounds normal. I concluded it was a gastric attack, and that she must have eaten something that had disagreed. At 7 P.M. I telephoned and heard that she was better, but still retching from time to time. Later she told her husband, who is a somewhat restless sleeper, that she thought she would sleep better alone. He consequently left her at about 11 P.M. and slept in the adjoining room. At 4.30 he awoke and heard her "coughing." He went into her room and found her sitting up in bed, with a basin in her hands, endeavouring to vomit. Hardly had he reached her side when she gave a gasp and fell back dead. At 4.45 A.M. (Monday, Sept. 9th) my telephone woke me up, and I was informed that she was dead. I was at the house before 5.30, when I learned the history of the night, and made sure that life was extinct.

*Necropsy.*—In the afternoon of the same day I made a post-mortem examination. The abdominal contents were normal, and in the thorax attention was immediately centred on the bulging pericardium. On puncturing it blood gushed out, and the sac was found to be full of blood, partly liquid and partly clotted. The heart itself was small, and the walls rather thin and pale. On the surface of the left ventricle, about an inch above the apex, was a dark circular patch rather smaller than a shilling, with a small rent in the centre. On section, the patch proved to be a collapsed aneurysmal dilatation; the central portion, where the rupture had taken place, was hardly thicker than brown paper. The obvious difference in colour and texture of the aneurysm from that of the rest of the ventricular wall seemed conclusive evidence that the lesion was one of old standing. In other respects the heart appeared normal. No microscopical examination was made.

I presume that what occurred on the Sunday was a pin-hole perforation, allowing of the oozing of droplets of blood into the pericardium, thus occasioning widespread vagal disturbance, and that the larger rent took place just before death.

The occurrence of such cases is valuable evidence of the astonishing capacity of some badly damaged hearts, and it is surely fortunate that these conditions cannot be diagnosed. Both of these patients lived useful lives to the very end. As

<sup>1</sup> The Bradshaw Lectures, 1883 (Med. Times and Gazette, 1883, ii., 199).

<sup>2</sup> Edinburgh Medical Journal, 1903, p. 322.

<sup>3</sup> THE LANCET, 1914, i., 533.

the lesion could not have been cured, any extra lease of life secured by rigid limitation of effort would have been dearly purchased at the price of invalidism, coupled by continual apprehension.

Tunbridge Wells.

## FLAVINE IN THE TREATMENT OF COM-MINUTED FRACTURES OF THE JAWS AND ACUTE SEPTIC STOMATITIS.

By H. WATSON TURNER, M.R.C.S., L.D.S.,  
DENTAL SURGEON TO THE MIDDLESEX HOSPITAL.

THE treatment of fractures of the jaws due to shrapnel or gunshot presents a complicated problem, special difficulties being extensive comminution of bone and laceration of soft tissues, and the high degree of septic infection. Provided the patients came under treatment before extensive necrosis of bone had occurred—i.e., not later than seven to ten days after injury—the results have been highly favourable in many cases with very severe damage and infection. I attribute my success in great part to the use of flavine, which has been shown to possess powerful antiseptic action in dilutions relatively harmless to tissue elements.

### *Method of Treatment.*

The following method was adopted as a general practice. After the patient had been anaesthetised a tube was passed into the larynx and the anaesthetic administered by means of it; the throat being plugged with gauze there was no possibility of foreign bodies passing downward. Teeth in the lines of fracture were removed wherever possible, and also every septic tooth and root. In dealing with fractured bone where comminution was extensive, it was impossible to decide which fragments were viable and which were necrotic. Accordingly I made a rule to leave all bony fragments undisturbed and to bathe and soak the whole fractured area for five to ten minutes with 1:1000 flavine solution, disturbing the parts as little as possible, so as to avoid mechanical injury to tissues already devitalised. The external wound was cleansed with flavine solution and dressed with gauze soaked in flavine, which was also used to pack lightly any sinuses. In fractured mandible the jaw was supported with a knitted chin support. Subsequent to this the treatment followed on the usual lines; cap-splints were fitted to maxilla and mandible and were wired together. Cleanliness of the mouth was ensured by frequent syringing.

I am convinced that the favourable results were largely due to the early treatment with flavine, which, hastening the extinction of septic infection, yet left unimpaired the vitality of the osteogenetic tissue. Had the living bone been destroyed in the course of treatment such complete bony union as occurred in these cases could not have been obtained.

### *Illustrative Cases.*

The following notes indicate the results in two particularly severe cases:—

CASE 1.—Pte., admitted Sept. 3rd, 1918. The X ray photograph showed very extensive comminution of bone; there was much destruction of soft tissues and profuse suppuration. After treatment on the lines described there was practically reconstruction of the mandible, as shown in a photograph taken on March 25th, 1919.

CASE 2.—Australian Lt. There was a fracture of the right maxilla with involvement of the antrum, which was filled with pus. The soft palate was badly lacerated, and the hard palate extensively comminuted; the mouth was very foul. The parts were cleansed with flavine and the antrum washed out with the solution, then all the soft tissues were soaked with flavine; all broken teeth were removed. At the close of the operation the soft palate was stitched up. It is to be specially noted that although the wound was completely closed, and no provision was made for drainage, the parts healed excellently and there was no recrudescence of sepsis.

### *Acute Stomatitis.*

The frequency of acute stomatitis of all degrees up to actual gangrene has been a striking feature among soldiers. These acute infections were usually superadded on a chronic septic condition of the mouth. When such cases first come under observation the gums are exceedingly tender and painful, and there is often extensive sloughing and an exceedingly foul odour. It is essential to get rid of the

acute inflammation before instituting thorough operative measures.

The following method of preliminary treatment has yielded excellent and rapid results:—The mouth is syringed out with flavine 1:1000, special attention being paid to all pockets. Then gauze soaked with flavine solution is lightly packed into the angle of the cheek and all round the gums, and is retained in the mouth for 20 to 30 minutes. This procedure is repeated thrice daily.

As regards the results, not merely is the application painless, but it leads quickly to relief of pain and to subsidence of the acute inflammatory condition. Further, in several cases where the mouth was so foul that one could readily detect the bad odour at a distance of several yards, 24 hours after commencing treatment with flavine the breath has become quite free from smell.

## Clinical Notes:

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### THE USE OF BISMUTH AND IODOFORM IN THE TREATMENT OF CHRONIC SUPPURATIVE OTITIS MEDIA.

By FRED. STOKER, M.B. DURH., F.R.C.S. EDIN.,  
AURAL SURGEON TO THE NATIONAL INSTITUTE FOR THE BLIND, AND TO THE ACTON EDUCATION COMMITTEE; REGISTRAR, HOSPITAL FOR DISEASES OF THE THROAT, GOLDEN-SQUARE.

EARLY in 1916 I was introduced to the merits of bipp<sup>1</sup> by its inventor, Professor Rutherford Morison. The results he was attaining by its use in bone surgery impressed me very greatly, and I put into operation his suggestion of using it in mastoid work. The sequel more than justified our expectations, and encouraged me to use a powder of bismuth and iodoform in the same proportions as in bipp in certain cases of chronic ear suppuration.

*Types.*—Chronic ear suppuration may be divided roughly into the following types: 1. Those in which the suppuration is not confined to the tympanum, but has extended to the mastoid or the labyrinth. Although in acute suppuration the whole middle ear cleft is generally involved, this by no means holds good in the chronic stage. It is a common experience to observe the relief of mastoid pain and tenderness after tympanic drainage is established in acute cases, and it is equally common to open a healthy mastoid antrum when operating for the cure of chronic suppuration. 2. Cases in which naso-pharyngeal or tubal sepsis is responsible for the continuance of the suppuration. 3. Those in which the bony tympanum is carious. 4. Those in which the suppuration is limited to the mucous tympanum.

It is only in cases belonging to the last group that cure may be hoped for by local conservative measures, but such cases are extremely common. The usual method of treating them with syringing, mopping, "drops," &c., is discouraging. One is so completely at the mercy of the patient's attendants, and the effect of the "drops," even when they are correctly instilled, is so transitory, that it is difficult to expect a cure. The use of "bip"<sup>2</sup> to a great measure removes these handicaps.

*Technique.*—1. Establishment and maintenance of thorough drainage. In the generality of cases that is already present, very many "chronic ears" presenting but a rim of membrane or even none at all. 2. Removal of crusts, dead epithelium, and all morbid material with hydrogen peroxide. 3. Thorough cleansing of meatus and tympanum with spirit, applied on a wool-carrying applicator, and allowing to dry. 4. Covering the tympanum with bip. The powder is blown in with a fine-pointed, slightly curved, powder-blower through a large speculum. In cases with profuse suppuration I have not found that more than three applications a week are necessary, and in milder ones a weekly application fulfils

<sup>1</sup> Bismuth, iodoform, and paraffin paste, containing bismuth and iodoform in the proportions of 1 of bismuth to 2 of iodoform.

<sup>2</sup> Bismuth and iodoform powder.

requirements. As the suppuration lessens the need for frequent sittings diminishes, of course.

**Results.**—I have treated well over 200 cases on these lines, and while 100 per cent. of cures cannot be claimed, the results have, in the great majority of cases, been so satisfactory as to justify my recommending the method. The curative effects may be attributed to two causes: 1. The continual antiseptic action of the nascent iodine, which is being constantly formed from the iodoform. 2. The prevention of putrefaction in accumulated secretions by the same agency. The factor of putrefaction is an extremely important one in chronic suppuration.

Long duration of the condition is no bar to success. Many of the cases successfully treated have suffered seven and eight years. The presence of a polypus need not always cause dismay; it is not conclusive evidence of bone disease, but its removal is necessary before thorough treatment can commence.

Queen Anne-street, W.

#### A NOTE ON

#### DUPLICATION IN HUMAN SPERMATOZOA.

BY S. R. TATTERSALL, M.R.C.S., L.R.C.P.

IN spermatozoa from certain of the lower animals partial doubling of the tail has been described as an occasional occurrence; but similar observations in the human subject seem to be at present wanting. In the case to which this note refers, the patient was a man, 25 years of age, suffering from spermatorrhoea. The microscopic examination was made upon films fixed by heat and stained, for ten minutes in hot carbol-fuchsin. This was found to stain the tails of the spermatozoa extremely well, but at the expense of some detail in the head and middle part.

The greater number of the spermatozoa are normal, but in a few instances one head is furnished with two distinct tails. The tails are quite separate and distinct as far forwards as the posterior end of the middle part, with which they join. The position of the two tails varies widely. Some lie close together, while others diverge at varying angles. The

Human spermatozoa, showing two-headed and two-tailed varieties. 1/12 in. oil-immersion. (Figure reduced.)

possibility of two heads and middle parts overlying each other has to be excluded, but the head-cap of the two-tailed forms is not less translucent than the head-cap of normal sperms. In each case the middle-piece is not increased in thickness. The tails have been of equal length with the exception of one sperm, where they differ markedly. The proportion of two-tailed to normal sperms is estimated at about 1:750. Those sperms which have been observed have all been in thin parts of the film where confusion with the tails of neighbouring spermatozoa may be with certainty excluded.

A second type of abnormality was also observed. One or two spermatozoa were furnished with two heads and one tail. The angle made by the axes of the heads varied from about 60° to about 170°. They are much less

frequent than the first type described, the estimated ratio to normal spermatozoa being about 1:5000. In a few of these two-headed spermatozoa the middle part appears of normal thickness, but in many it is slightly thicker, though not denser than that of the normal spermatozoon. The genuineness of this type is, however, not indisputable. Several instances have been observed where with divergent heads, the middle parts and tails have adhered very closely, indeed diverging only for about the last eighth of their length. Although these latter are probably spermatozoa adherent to one another, the possibility of their being fused by the middle part may be borne in mind.

No abnormality has been found in the sexual history of the man's family. There has not been a marked preponderance of one sex among the children born, nor has there been an instance of twins or abnormal children for two generations back. The drawings were made under Professor Shattock's supervision, and he informs me that the occurrence of two-headed spermatozoa in the seminal fluid of man was recorded by Major F. Smith in the *Journal of the Royal Army Medical Corps* (Vol. XI., 1908), though without either particulars or drawings: the individual is stated to have regularly procreated twins.

Schäfer<sup>1</sup> states that in animals the extremity of the tail may be split into two or three fibrils, which can sometimes be traced along the whole length of the tail. The drawings accompanying this communication were made with a 1/12 in. oil-immersion objective, and a 10 x eyepiece.

Since the above observation was made I have found similar two-tailed forms in the fluid from a spermatocele. The opalescent fluid, which contained great numbers of spermatozoa, was diluted from normal saline, and from this preparations were made as above described.

St. Thomas's Hospital.

#### CASE OF SMALL-POX SIMULATING ACUTE APPENDICITIS.

BY J. K. HAWORTH, M.D., B.S. DURH.,

CAPTAIN, R.A.M.C. (S.R.); SURGICAL SPECIALIST, 8TH LUCKNOW DIVISION.

THE following case of small-pox appears to illustrate the difficulties of diagnosis in acute appendicitis.

Mrs. — was admitted at 10.30 P.M. to Family Hospital, Lucknow, complaining of acute pain in her right side, with vomiting and fever—the Murphy sequence. Her history was that she had been unwell for three days, but only on the day of admission had she thought it necessary to call in medical advice. On admission she was in great pain, temperature 104.6° F., pulse 100, with vomiting. The rate of breathing was slightly increased. Her abdomen was not distended; she was very tender over the appendix area, with only slight rigidity. Chest normal. The case at first appeared one of acute appendicitis, but it was decided, not without considerable anxiety, to delay operation till next morning, as her general condition and abdominal signs did not seem quite to agree. Next morning she developed a typical small-pox rash with some hæmorrhagic spots. Her temperature dropped. The pain disappeared and the course of disease was uneventful to recovery.

In striking contrast to this case on the next day a patient in hospital developed almost exactly similar symptoms and was operated on in less than 12 hours from his first attack of pain, and a black gangrenous appendix was removed.

<sup>1</sup> Essentials of Histology, 1914, p. 389.

A PSYCHIATRIC CLINIC FOR CARDIFF.—A conference was recently held at the City Hall, Cardiff, attended by Sir William Byrne and Dr. C. H. Bond, on behalf of the Board of Control, at which the setting up of an in- and out-patient department for early mental cases in connexion with King Edward VII.'s Hospital was fully discussed. The proposal is, in the first instance, for a psychiatric clinic of 50 beds within convenient reach of the infirmary, with facilities for special examination and psychotherapy, as well as lecture rooms and laboratories. The out-patient department, it is expected, will be located at the King Edward VII.'s Hospital. Sir William Byrne, in expressing the sympathy of the Board of Control with the scheme, outlined the main features of the amending Bill to the Lunacy Acts, the draft of which is now being considered by the Government.

## Reviews and Notices of Books.

*The Story of English Public Health.* By SIR MALCOLM MORRIS, K.O.V.O. Pp. 166. *Infant and Young Child Welfare.* By HAROLD SCURFIELD, M.D. Edin., D.P.H. Camb. Pp. 166. *Food and Public Health.* By WILLIAM G. SAVAGE, B.Sc., M.D. Lond., D.P.H. Pp. 156. *Housing and Public Health.* By JOHN ROBERTSON, C.M.G., O.B.E., M.D., B.Sc. Pp. 159. *The Welfare of the Expectant Mother.* By MARY SCHARLIEB, C.B.E., M.D., M.S. Pp. 152. (English Public Health Series, edited by Sir MALCOLM MORRIS.) London: Cassell and Co., Ltd. 5s. each volume.

THE editor and the publishers are to be congratulated upon the timely appearance of this series of books dealing with the present problems of public health. It is designed especially to meet the needs of members of local authorities, district nurses, health visitors, and the lay public generally in so far as this public is interested in its own welfare. We hope that where that interest is lacking these books will do much to supply the want, for legislation can never be effective in public health unless it is supported by an intelligent body of opinion.

Sir Malcolm Morris, who also edits the series, is responsible for the first volume—a short history of the growth of the public health movement from the work of Edwin Chadwick, which culminated in the passing of the Public Health Act of 1848 down to the establishment of the Ministry of Health. The functions of the principal central health authorities in the old regime are dealt with serially; two chapters are devoted to the questions opened up in recent years by discoveries of the nature of the infections and the spread of venereal disease, and finally the Ministry of Health is invoked to embrace all the measures taken by old authorities as well as to deal with the new problems as they arise.

The welfare of the infant is viewed by Dr. Scurfield from a very broad standpoint, and is exactly the kind of writing which is most needed. In his introduction he reviews the doctrine of the survival of the fittest as becomes a disciple of Benjamin Kidd, and wonders how many useful citizens the Spartan Council of Elders ordered to be thrown down the cavern of Mount Taygetus. If we are to assist in the survival of the fittest it must not be by neglecting the weak, but rather by paying attention to eugenics. Dr. Scurfield recognises the limitations necessary to the application of this science, but does powerfully plead for some endeavour to prevent the marriages of syphilitics, epileptics, alcoholics, mental defectives, and persons suffering from an infectious stage of tuberculosis. From its heritage the writer passes to a consideration of the baby's environment, and thence to a very practical review of the details which make its life worth living. This is a volume which every mother and every intending mother ought to study.

When the second edition of "Food and the Public Health" comes to be published it is reasonable to suppose that a great deal of new matter will have to be introduced into the first chapter. In the present edition the food constituents are classified and the common foods are considered as regards their caloric value and digestibility. But the newer knowledge acquired during the war of the effects of certain foods in counteracting fatigue and the results of the deprivation of others through war conditions—all this is perhaps not yet sufficiently crystallised to find expression in popular language. The remaining chapters deal mainly with the adulteration and infection of food, and are illustrated by half-tone plates.

Dr. John Robertson writes as one having authority, for he depends mainly upon his own experience as a medical officer of health in one of our most crowded cities, and quotes but seldom from the works of others, though a useful little bibliography is appended. The bad housing of the past was due to poverty. Never again, says Dr. Robertson, must the labourer be allowed to suit the house to his wage. Public attention has already been closely focussed upon the evils attendant on bad housing, and it is a relief, therefore, to find that the scope of this book is almost entirely constructive. The minimal standard for a dwelling-house as laid down by the author is certainly not too high, he writes as a practical man rather than as a seer, and in our opinion his plea for the use of electrical labour-saving devices is almost too apologetic.

The welfare both of the expectant mother and of her child depends to a very great extent upon the care devoted to them in the antenatal period, and the first step towards or diminution of the risks incurred by both is, as Dr. Scharlieb says, in the direction of popular education. Dr. Scharlieb has long practised what she preaches, and the gravamen of this book has formed the substance of her writings and lectures for many years. All the popular aspects of pregnancy, with its demands and its dangers, are dealt with in her usual incisive style. She pleads for a larger number of midwives, increased hospital accommodation, and the multiplication of welfare centres, and recommends that facilities be increased for the investigation of the causes leading to antenatal death. A scheme for the endowment of motherhood is also on her list of desirable reforms.

We have said that these books are intended for lay readers, but there is no doubt that they will also prove of interest to many medical men.

*Anaphylaxis and Anti-anaphylaxis.* By A. BESREDKA. With a preface by E. ROUX. English edition by S. ROODHOUSE GLOYNE, M.D. London: W. Heinemann. 1919. Pp. 143. 6s.

IF any reader considers anaphylaxis to be a dull topic he should read this gay account by one who has been in the thick of its experimental investigation almost from the first. And anyone who thinks it a difficult subject may do the same, for the exposition is forcible and for the most part clear enough, the whole finding an admirable summary in the preface by Roux. It is some 17 years since Richet had the idle curiosity to call in the dog Neptune to help with the poisonousness of his extracts of sea-anemones, and—which is the basis of most great discoveries—the wit to see that he had found out something more than that experiments do not always come off. Arthus made further progress, though it was not till Rosenan and Anderson brought "Richet's phenomenon" into the restricted field of pathological vision by using the familiar serum-guinea-pig apparatus that the stream of inquiry fairly began to flow, and finally almost flooded us out. Besredka takes the phenomena seen with egg-white, serum, &c., and the guinea-pig as typical, and describes in order the circumstances of sensitisation by a first injection, of exciting anaphylactic shock by a second injection, of desensitisation by a vaccinating or anti-anaphylactic injection, and finally discusses the theory of the whole business. The view he takes is that now pretty generally admitted: the first injection of a proteid causes the production by the recipient animal of an antibody, which he frankly assumes without clear evidence to be a special "anaphylactic antibody." The second injection, given after an interval in which this "sensibilisin" accumulates, either in large amount, or in curious places, or in both, reacts as any antigen will with its antibody, and, either by the violence of this reaction or on account of the place where it occurs, general symptoms of greater or less severity ensue. These symptoms may be avoided if, quite shortly before the second injection, a small dose of the antigen is given, and Besredka points out at some length how easily the anaphylactic troubles of serum therapy may be minimised by his method of small preparatory injections of serum preceding the main therapeutic dose by 10 minutes to 3 or 4 hours, according to the route of administration. The method seems to deserve special consideration now that, e.g., meningitis and pneumonia are being treated with doses of serum undreamed of a few years ago.

With regard to the mechanism of production of anaphylactic shock, the author will have none of Friedberger and the anaphylotoxin he has so profusely propagated. He says, indeed, bluntly that there is no anaphylactic poison; that the union of antigen and antibody results in a harmless complex, and that the disturbance is produced by the antibody becoming attached to, and so enabling the antigen to penetrate, certain nerve cells. Here he is vague. The question at issue seems to be not whether there is a poison or not—unless the cellular injury which objectively occurs is mechanical in origin there must be something somewhere which might be called a poison—but whether the reaction which results in the shock takes place in the fluids of the body or inside the cells. Friedberger would say that the combination of antigen and antibody in humore gives a poison, Besredka that it upsets cells because it takes place inside them. The two views are not necessarily mutually exclusive; both parties are, as usual, probably more or less

right, and likely the truth is that the reaction takes place inside cells, and on that account liberates poisonous substances which may act generally as well as locally.

A good many details are naturally, and commendably, left unnoticed; some of the more important recent advances are described in a supplementary chapter by Dr. S. R. Gloyne. The enthusiasm of the narrative leads to a few statements which can hardly be taken at their face value—e.g., that passive anaphylaxis takes place “instantaneously.” There is a sad misprint on p. 18, where, at its definition, sensibilisin is called sensibiligen. Neither the title-page nor preface is dated.

*Mammalian Physiology: A Course of Practical Exercises.*

By C. S. SHERRINGTON, M.D., D.Sc., F.R.S., Waynflete Professor of Physiology in the University of Oxford. Oxford: At the Clarendon Press. 1919. Pp. 156.

Professor Sherrington, recognising the fact that a certain broadening of scope of the practical work customary for students in animal physiology is desirable, has in this manual given an admirable response to this desire. The work is correctly described as a course of practical exercises in mammalian physiology, the emphasis being on the word mammalian. In most medical schools what is called “experimental physiology,” as carried out by the students themselves, is usually confined to muscle-nerve preparations and the cardiac and spinal physiology of the frog, and but rarely does the student make experiments on a mammal—save on himself. Professor Sherrington does not propose to do away with laboratory experiments on the frog. But he sees that there are other facts of great value and interest, especially to the future practitioner of medicine, which can be better displayed and more easily obtained in the mammalian preparation, and thus, with elaborate detail, describes how in Oxford for some time he has met this proposition. Building on the fact that in a decerebrate or decapitate “carcase”—e.g., rabbit or cat—the circulatory, glandular, muscular, and simpler nervous activities remain for some considerable time, a scheme whereby the student can observe, study, or record, if need be, these activities became possible; but in this course the great fact is that the student does the work himself—it is not a question of a mere demonstration by the teacher—so that by the actual performance of these main experiments he gets a genuine insight into their general significance and into the problems they touch. Moreover, the systematic knowledge acquired from text-books is vivified as well as vitalised, and the interest in their studies intensified and thereby made a living and abiding possession of great practical value where practical work has actually been done.

The course comprises 21 lessons, each consisting of somewhat less than three hours' work. In each lesson certain “observations” have to be made, and full details for these are given, the instruction being greatly aided by anatomical and other notes set forth in nine plates in colour admirably drawn by the author himself, diagrams of apparatus, and graphic records in the text, reproduced from the tracings obtained by the class students themselves. To each exercise is subjoined a short annotation concerning the source and bearings of some of the more salient observations included in the exercise. Their trend is often historical, and many references are given to publications in which additional details are to be found. By way of showing how all these observations can be carried out on the “carcase,” and how they can be so arranged as to obtain the maximum profit from each animal utilised, an appendix is added at the end of the volume. There is an index of the names of authors referred to in the text, but with rare modesty the author omits his own name, though there is scarcely an exercise to which he himself has not made some original contribution.

Ninety-five “observations” are comprised in the 21 “exercises.” The idea of the extraordinary scope of the work done in about 60 hours can be best grasped by a limited epitome of the main experiments. Given a “decerebrate” or “decapitate” carcass of rabbit or cat—no dogs are used—the first exercise comprises the study and recording of intestinal movement and tone, with the action of adrenal extract on these and on the excised spleen and arterial wall. The circulation next is taken in hand, comprising revival of the excised heart by coronary perfusion; the influence of temperature, adrenalin, and chloroform on the excised heart; inspection of the lungs,

great vessels, and the heart beating in situ; vagus inhibition, and effect of raising the intra-pericardial pressure. Then follow graphic records of arterial pressure by the kymograph, and the effect on heart and blood pressure of stimulation of the vagus and spinal cord and splanchnic nerve; “vagus escape”; the action of atropine, adrenalin, amyl nitrite, pituitary extract; asphyxia; artificial aortic stenosis and insufficiency; time of the lesser circulation, action of the accelerans on heart rate, and other cardiac phenomena. Renal secretion, hydræmic plethora, diuresis by caffeine citrate, effect of pituitary extract, perfusion of the kidney with normal saline, and the action of adrenal extract and amyl nitrite with cognate subjects occupy two exercises. Next salivary secretion—corda stimulation—and the action of pilocarpine and atropine are studied. Then follow observations on respiratory movement and allied phenomena; respiratory rhythm and the effect of nerves thereon; air-embolism, pneumothorax, respiratory undulations of blood pressure, and the various reflexes connected with the glottis, and swallowing in its various aspects.

Pressor and depressor phenomena are then dealt with, and so are other reflexes. This leads up to knee-jerk functions of the spinal roots and other spinal phenomena, cervical sympathetic action, proprioceptive reflexes, measurements of reflex and twitch, postural tone, and reflex inhibition of posture and contracture. Hæmorrhage and arterial pressure and restoration of the latter by gum-saline injection, clotting, and fibrinogen are all described. One exercise is given to “washed leucocytes,” phagocytosis, and opsonic power of serum, and another to preparation of secretin, pancreatic secretion, and bladder-bile. Fortunate indeed are the students who obtain such a compendious, practical, and vivifying course of instruction in applied physiology. We most cordially endorse the view of Sir George Newman that these exercises are an illustration of the kind of applied physiology which should be taught in all schools of physiology.

As was to be expected, Professor Sherrington has done his work with a master hand. If we compare the operative training and the vast amount of knowledge directly and personally acquired during 60 or 70 hours spent in a well-equipped physiological laboratory with the modicum of anatomical detail acquired during the same time in the dissecting room, there seems to us to be no doubt as to where and how the medical student can most profitably spend what after all represents less than three full days of his academic time.

*Modern Medicine and Some Modern Remedies: Practical Notes for the General Practitioner.* By THOMAS BODLEY SCOTT, M.R.C.S. Eng., L.R.C.P. Edin. Second edition. London: H. K. Lewis and Co., Ltd. 1919. Pp. xvi. + 198. 6s. 6d.

THESE essays were first reviewed in our columns in September, 1916. It is no surprise to us that a second edition should have been called for. Dr. Scott writes in a style that is at once pleasant to read and that carries with it the confidence of the reader, who feels instinctively that the author has used his observation not only at the bedside but also in the laboratory, and that he has used it with a shrewd discrimination. In dealing with such ailments as heart disease and chronic bronchitis the general practitioner learns much that was never taught to him as a medical student, and many who are setting up in practice at the present time will be the wiser by borrowing from Dr. Scott's well-stocked store of common-sense.

## JOURNALS.

*Quarterly Journal of Experimental Physiology.* Editors: E. SHARPEY-SCHAFER, W. D. HALLIBURTON, C. S. SHERRINGTON, E. H. STARLING, A. D. WALLER. Vol. XII., No. 2. London: Charles Griffin and Co. 1919. Pp. 97-198. 7s. 6d.—Carbohydrate Metabolism in Relation to the Thyroid Gland (IV.): The Effect of Thyroid Feeding on the Gaseous Metabolism of Thyroidectomised Rats, by W. Cramer and R. McCall. Such animals react to thyroid feeding by an increased metabolism, but this experimental hypothyroidism shows two stages. In the early stage in which the metabolism is reduced if thyroid gland is administered the metabolism is brought back to that of the normal animal; in this respect it is similar to pathological hypothyroidism. In the later stage the metabolism is similar to that produced in a normal animal by thyroid feeding. This result seems to be due to a compensatory mechanism, and does not really represent a condition of true hypo-

thyroidism. The increased metabolism due to thyroid feeding occurs also in the absence of preformed carbohydrate in the food. It appears that all changes in metabolism can be explained as being the result of disturbance of the glycogenic function. It is suggested that in Graves's disease a diet rich in carbohydrates is indicated to counteract the loss of flesh which is one of the features of the disease.—The Action of the Blood-serum of the Dog in a Condition of Tetania Parathyreoopriva on Voluntary Muscular Tissue compared with that of Normal Serum, by B. A. Houssay. Neither of these serums causes tremors in the muscles of the South American frog (*Leptodactylus ocellatus*). Five out of six samples of tetania serum produced tremors in the muscles of a toad (*Bufo marinus*), while four samples from normal dogs produced tremors. On the other hand, four other samples from normal dogs produced no effect.—The Adrenalin Content of the Suprarenals of the Female White Rat and the Changes Brought about by Thyroid Feeding and other Conditions, by P. T. Herring. The suprarenals of young female white rats are normally 40 per cent. heavier than the suprarenals of the male animals of the same weight, while the adrenalin content of the suprarenals of the female is twice as large as that in the male of the same size—e.g., average adrenalin in female 0.073 mg., in male 0.034 mg. These differences are associated with sex differences in the other endocrine glands and organs of the body. The adrenalin content is increased during pregnancy, but is not permanently altered by the occurrence of this condition. The female white rat is less tolerant of thyroid feeding than the male; a daily dose of 0.2 g. fresh thyroid if continued is too high and checks the rate of growth of the animal. Thyroid feeding causes a rapid increase in the weight of the suprarenals, but more so in the male. The chromaphil tissue of the female rat normally contains a much higher level of adrenalin production than it does in the male. The increased size of the suprarenals following on thyroid feeding is mainly due to hypertrophy of the cortex. The percentage amount of adrenalin is always diminished by thyroid feeding.—The Effect of Phloridzin on the Permeability to Glucose of the Frog's Glomerular Membrane, by R. Brinkman. The surviving kidneys of the frog were perfused with certain solutions of known composition—e.g., Ringer's fluid—and the result showed that frog's glomerular membrane is, under normal conditions, impermeable to physiological quantities of glucose. The "urine" obtained was compared with the fluid perfused. The rate of diuresis had no influence on the results. So far as glucose was concerned—the urine obtained always contained the percentages of glucose (0.05–0.1 per cent.) in the perfusing liquid. Further experiments showed that the permeability of the glomerular membrane is dependent on the composition of the perfusing fluid—the concentration of the free Ca-ions is the factor of greatest importance in this connexion. If the Ca-ions have a certain concentration the membrane shows itself impermeable to physiological quantities (0.06 per cent.) of glucose. If the concentration exceeded 0.003 per cent.  $\text{CaCl}_2$  the membrane became permeable to glucose. A second factor is the preservation of the normal slight alkaline reaction of the perfusing liquid ( $= 0.285$  per cent.  $\text{NaHCO}_3$ ) = to that of frog's serum. As to the action of phloridzin, it is known that phloridzin-glycosuria is a renal process, most investigations finding that blood-sugar is not increased, it may even be decreased—i.e., hypoglycæmia. Many suppose that this drug causes the tubuli to secrete glucose. It was found that the addition of 0.0004 per cent. of phloridzin to the solution already described is sufficient to make the otherwise impermeable membrane wholly permeable to physiological quantities of glucose, though the membrane is not influenced by many other drugs—e.g., atropin, pilocarpin, nicotin, narcotics. The concentrations of the glucose in the urine closely follow those in the corresponding serums. Phloridzinised frogs show well-marked hyperglycæmia. Phloridzin promptly makes the glomerular membrane permeable to glucose. In higher animals secretion of glucose by the tubuli is the dominating phenomenon.—A Convenient Method of Recording Pulmonary Blood Pressure, by Sir Edward Sharpey Schafer. The method was used in some of the experiments described in the Effects of Adrenalin on the Pulmonary Circulation, by Sir Edward Sharpey Schafer and R. K. S. Lim. The intravascular administration may produce effects on the pulmonary circulation by (1) an effect on the pulmonary arterioles, causing constriction, or in some cases dilatation of these vessels, resulting in a diminution or increase of the flow and a rise or fall of the pressure in the pulmonary system; (2) on the musculature of the heart through the sympathetic nerve and coronary vessels; (3) on the conducting (Purkinje) fibres under the endocardium; and (4) indirectly as a consequence of constriction of the systemic arterioles and great rise of the aortic pressure. The effects produced upon the aortic system can be similarly caused in four ways. First the effects of perfusing adrenalin through the surviving lung

were studied. The results of previous observers are not in accord. In the rabbit adrenalin in moderate doses injected into the jugular vein usually at first causes a rise of pulmonary blood pressure, owing to constriction of the pulmonary arterioles, or shows no effect on this system. If there is great constriction any rise in the pulmonary system is soon converted into a fall, gradual recovery following as the constriction passes off. The effects are similar when it is injected into the aorta through the carotid, but the preliminary rise is absent. In the cat the usual result is a sharp, well-marked rise in both pulmonary and aortic pressures—and usually with parallelism in both systems—which must be of cardiac origin. In the dog there is a great rise in both systems, sometimes running almost parallel. The rise in the pulmonary system is not due to "back action" propagated from the aortic system. There may be no rise at all in the pulmonary, with great rise in the aortic systems, even when the aortic pressure is raised by compression of the aorta and in other ways. In rabbits the chief effects of adrenalin upon both pulmonary and aortic pressures are produced upon the blood-vessels, but in most cats and dogs the chief effects are produced by the drug upon the cardiac musculature. The musculature of the two sides of the heart may be differently affected by adrenalin, which may be due to its action on the Purkinje network of the ventricles.—The Effect of Adrenalin on Muscular Fatigue in *Leptodactylus ocellatus* and in *Bufo marinus*. By John Guglielmetti. Subcutaneous or intravenous injection or perfusion produces recovery of muscular contractions which have been abolished by previous fatigue. Given sufficient doses recovery may be obtained in muscles which have been wholly exhausted. Recovery is more usually obtained when the adrenalin is made to act early upon the preparation.—Note on Strychnine Tetanus. By Arthur R. Cushny. The author's experiments lead him to conclude that it is unnecessary to assume, as has been done, that strychnine changes the ordinary coördinated reflex, not only in quantity, but also qualitatively, by inducing a reversal of inhibition into contraction. Strychnine tetanus is merely a quantitative change of the "start" reflex which occurs under normal conditions.

## New Inventions.

### A VENTILATING ETHER BAG MOUNT.

THE accompanying illustration shows a bag mount designed to afford an inhalation as "open" or "closed," as the administrator may wish. A fits Hewitt's wide-bore inhaler and face-piece. An Ormsby (or paper) bag is attached over the cage C by a thick rubber band. B opens a window, simultaneously cutting out the bag to any desired extent. T admits gas, oxygen, or ethyl chloride to the bag, whatever the position of B, and is removable for cleansing purposes. R, fixed to T, is pushed home into A for use. Gases can be retained in the bag by opening B and closing T by the stopcock S. This affords a convenient means of giving ethyl chloride either alone, or before ether, the bag being

charged before applying the face-piece and gradually opened as the window at B is being closed. For the gas-ether sequence a little hot water can be poured into the Ormsby through A. With less than two ounces of ether anaesthesia can then be induced in about three minutes, usually without appreciable coughing or struggling. During the operation B is always more or less open, so that with every breath the patient gets some fresh air, as warm and moist as the anaesthetist may desire. The hot water in the bag can be easily renewed or the bag may float in a bowl of hot water. The mount (and bag) can be boiled, there are no valves to get out of order. By means of an "adapter" the mount may be adjusted to an ordinary "Clover" or face-piece. I have used this apparatus for brain cases and abdominal operations of every kind during the last five years. It is made by Messrs. Barth.

LONDON: SATURDAY, AUGUST 2, 1919.

## Science and Unrest.

TRULY these are progressive times, when we find labour organisations demanding State aid for scientific research on the ground that the value of scientific advancement to the welfare of the nation is many times greater than the cost of the necessary laboratory quest. Public recognition of this fact will mean the era of a great movement of the utmost social and economical importance. When it is realised that increased productivity of industry results from scientific research, a powerful aid will appear to those involved in an ever increasing struggle to raise their standard of living. In applied science there lies a possible solution of many disastrous labour problems, and none too soon those who labour are perceiving it. Have they not seen the truth before their organisers or their employers?

In a remarkable manifesto on scientific research recently drawn up by the American Federation of Labour it is maintained that the importance of scientific applications in industry must steadily increase, since there is a limit beyond which the average standard of living of the whole population cannot progress by the usual methods of readjustment, a limit which can only be raised, it is claimed, by research in industry. The wise solution of the numerous important and pressing problems of administration and regulation now facing almost all Governments of the world depends, it is suggested, upon scientific and technical research. It would be a remarkable consummation in the history of the world, as is here hinted, should science ultimately prove to be the palliative of unrest. And it seems probable, if we accept the application of science to mean increased production and output of what is essential to the existence and welfare of both workers and community. This may be a truism and altruism well worth the serious thought of our counsellors. The community has its claims on medical science also for maintaining the health and well-being not only of the workers but of the whole population, which is thus dependent upon scientific advances in medicine and sanitation. Without research progressive medicine is, of course, impossible, and medical science could not have reached its advanced stages without intensive studies along all sorts of ancillary lines; and similarly progressive industry and output must be dependent upon deeply searching and minutely inquisitorial work. The war has brought home to us the fact that the world has ignored a great asset brought into valuation by the pursuit of knowledge; the war was largely won by applied science, and it is to science properly applied that the world looks for regeneration. The British Labour Party has recognised this, and its advisory committee on public health has urged on the Ministry of Health as one of its main duties the direct prosecution of medical research and its encouragement in universities and elsewhere.

Here is a concrete example to which we referred last week—namely, the encouragement of research work in drugs by the State, which resulted in great

advantages to the country. At the outbreak of the war there was a threatened famine in essential drugs, the supply and preparation of which had hitherto been left entirely to enemy sources. The National Health Insurance Commission were fully alive to this fact and to the possibility of disaster looming ahead on this account; but with the assistance of the Royal Society and various State departments scientific workers and manufacturers were brought into touch with each other. The result was that there was no drug famine, no really important medicine was lacking for essential purposes, and at no time did the public health suffer from a lack of medical and surgical material. What was done by the State in encouragement of one particular and important industry in a time of emergency should obviously be continued with benefit to all the economic and industrial resources of the country now that the war is over.

## Psychiatric Clinics.

THE essential mystery of mental disease baffles us now as it did a century ago, and Dr. BEDFORD PIERCE, in his presidential address to the summer meeting of the Medico-Psychological Association, queries whether the recovery rate has increased during that time. But signs are not wanting of encouragement. During the past year several medico-psychologists have been earnestly engaged in framing recommendations for the more rational treatment of patients suffering from incipient mental disease. It is satisfactory to note that the result of their labours is likely to bear fruit in the near future. The experience gained in the special hospitals for similar cases under military organisation has served to bring to a focus what has long been held to be desirable in civilian practice. But to attain this objective no proper provision exists, as is well known, neither is there legal sanction. The prevention of disease is as much the rôle of the practitioner as is the cure and care of patients. To this end the sooner a case of threatening mental breakdown can be dealt with the better should be the result secured; and it is not too much to hope that insanity may yet be nipped in the bud to no small extent. The extension of the voluntary boarder principle to the county and borough asylums, which is being promoted, is a step in the right direction, but there is a large class for which other facilities for early treatment must be devised. The establishment of recognised homes for incipient or border-line cases, advocated by Dr. L. A. WEATHERLY last week, is, we think, generally approved, subject to notification to some public authority competent to exercise supervision. Such homes would apply to private patients in a position to defray the expenses incurred. But for the person of slender means the demand for psychiatric clinics seems to be imperative in order to keep abreast of the times.

Several of the voluntary hospitals, in response to appeals, have instituted out-patient clinics for mental cases, but apparently they hesitate to allocate beds for them. No doubt this would entail the building of an annexe, or, at any rate, the provision of a special ward with suitable arrangements, and the services of nurses with asylum training. It is quite possible that the overcrowded state of the hospitals militates against a departure which involves increased responsibilities and expense. Yet the advantages which should accrue are manifest

in bringing mental diseases into closer alliance with other diseases, and the consultations between the various departments would be of the utmost value. Moreover, the class-rooms and laboratories would be at hand, and there would be increased opportunities for the scientific teaching of psychological medicine. The finances of such a scheme for mental clinics might very fairly be met by contributions from the local authority or central exchequer, and this, we take it, is provided for in the legislation proposed by the Board of Control. The union infirmaries, to which the poorer classes of mentally affected patients in the first instance have access on certain conditions, can scarcely be held efficient under the present regime. The medical and surgical staffs are inadequate, there is a need for workers in pathology, and their status would be improved by the appointment of a recognised authority on psychiatry to direct the treatment of mental cases. In the interests of public health mental patients should be able to obtain early treatment without the formalities of the three-day order and certification, which, with the added stigma of pauperism, have such a baneful influence on persons in the incipient stage of insanity. Reform can only be achieved by dissociating the management entirely from the Poor-law in name as well as in fact. Were this accomplished, it is more than probable that many existing buildings could be remodelled and adapted for the formation of psychiatric clinics, in addition to those which the voluntary hospitals may in time provide, and where medical schools exist in the vicinity they should be affiliated to the clinics for the purposes of teaching and research.

But besides these problematical innovations there is yet another method to deal with the situation, which has already been initiated, and that is to build hospitals for incipient nervous and mental diseases analogous to the special hospitals that exist for other diseases. There is much to be said for this movement, and it might save the cost of the continual additions to the asylums of the country. These hospitals should constitute thoroughly up-to-date psychiatric clinics with every means for scientific investigation; care should be taken that they are bereft of any tinge of asylum atmosphere, or they might defeat the object in view. The Maudsley Hospital, which is equipped with modern laboratories, already exists owing to the foresight of its munificent donor, and it is to be hoped that no time will be lost in admitting suitable patients on a voluntary basis when the military authorities have evacuated it. The meetings of delegates of the various asylums' committees of the country which took place at the Guildhall this year on the problem at issue have resulted in good work, and we observe with satisfaction that it is proposed to institute a psychiatric clinic at Cardiff, to which allusion is made in our news columns. By such means we may, as Dr. EDWIN GOODALL suggests in his letter, remove the reproach at present resting on psychiatry in this country. For the moment, however, there is this difficulty to be faced. The functions of these clinics, and more especially of approved homes, can scarcely be performed without risk in the present state of the lunacy laws. These and other cognate matters have received the careful attention of the Board of Control, whose recommendations are in close accord with those contained in the report of the Lunacy Legislation Committee of the Medico-Psychological Association. An amending Bill drafted by the Board of Control has

been, we understand, in the hands of the Government for some time, and it is regrettable that this measure has not been brought forward this session in connexion with the Ministry of Health. The position of the various administrative departments of health will require rearrangement under the new Ministry, and it would seem feasible for lunacy to come within its province, a course rendered possible by an Order in Council. The transfer, if effected, should not interfere with the duties of the Board of Control, whose work in administering the present Acts is fully appreciated, and we are glad to find that the Board is in sympathy with the new aspirations for more rational means of treating the early stages of mental disease.

### Medical Trade-Unionism.

THE Annual Representative Meeting of the British Medical Association was held last week under the presidency of Dr. T. W. H. GARSTANG, the Chairman of the Representatives, and, as might have been expected, having consideration to the times in which we live, the trade-union question in reference to the medical profession was treated as an important issue. A recommendation was received from a large provincial branch that the British Medical Association should not endeavour to prevent its members from joining any other organisation which was attempting to combine the profession on trade-union lines, the reference clearly being to the Medico-Political Union, a body which is frankly committed to trade-union principles. Speeches were made by some who had already given in their adherence to the Medico-Political Union, and although their arguments were not perhaps conclusively dealt with, the vote showed that the British Medical Association, through its Representatives, disagrees in great majority with any attempt to convert the profession of medicine into a trade-union. It is no reproach to clear thinking, or to the debating powers of either side in the controversy, that nothing was said proving the one side to be wholly right or the other side to be wholly wrong; the arguments for the introduction into medical practice of trade-union principles are very strong, but the arguments which can be employed in opposition are at least equally strong; and it is a great error on the part of those who see salvation in the formation of a trade-union to insist that those who dissent from them are influenced only by motives of obsolete snobbery.

That a trade-union may be an effective weapon capable of good use and capable of gross abuse we all know at the present day, but its virtues and its defaults have been displayed in association with callings which cannot be compared with the calling of medicine. The analogies usually employed in this controversy are imperfect. A trade-union must be substantially a union of those employed in the trade, though no doubt every trade-union has among its supporters dissentients who now and again form a considerable body of opinion. None the less, the members have a common policy, and by effective weapons which are within their reach can stimulate political activity along the desired lines. The medical profession cannot have a common policy except in the carrying out of the grand ideal to serve humanity. Certainly in the pursuit of this ideal medical practitioners have the right to formulate a common demand for proper remuneration, and this demand depends for its real force upon no vaporous or sentimental claim to the

gratitude of the public, but upon the undeniable argument that good service can only be rendered by men who are placed in a proper position to do good work. Where that work is multifarious it is exceedingly difficult to devise a plan to insure that along each and all the lines justice is being done. Clearly no single rate of wages, with which a trade-union is so well able to deal, would meet the case. It is generally admitted that the most ardent advocates of medical trade-unionism have no intention of using the last weapon of the trade-union—namely, the strike; but a proposal to substitute for the strike against individuals a strike against Government regulations may be a distinction without a difference. A recent memorandum by the Medico-Political Union states that panel practitioners are the only citizens in this country who are, at the present time, outside the protection of the law, the statement deliberately excluding the position of the Civil Servant. It is conceivable, and indeed conceded, that a large body of the medical profession, being engaged in homogeneous work by a common employer, form typical material for a trade-union, and in this sense is doubtless to be construed the National Insurance Defence Trust to be administered by the British Medical Association. But what is to be the attitude of other members of the medical profession not in the same position? They cannot be forced into a trade-union, and their scientific and humanitarian services must be available for the benefit of medicine as a whole, within and without its sections.

It was to assist in the solution of such questions that the Medical Parliamentary Committee was formed, and if in its present shape as a British Federation of Medical and Allied Societies it should become representative, the medical man through any body, association, or group with which he is affiliated, would give a vote on these great questions and inaugurate a policy of strength and of conciliation. But it is understood that the British Medical Association, within whose ranks a difference of opinion on the trade-union question has become manifest, will not revise its opinion that this Federation has no reason for its existence. The British Medical Association is the elaborate work of men devoted to the interests of the medical profession, and every respect must be paid to their decision; but here is a question of vital importance upon which apparently members of the Association do not think alike. If the trusted leaders of the Association would debate this and cognate questions with a real federation of medical and allied bodies good would emerge.

THE Government's intention to regulate the sale of products which in the past were limited by patent was made by Sir Auckland Geddes, President of the Board of Trade, in the House of Commons on July 28th, on the occasion of his moving the second reading of the Trades Marks Bill. In what he said he was guided probably by the recommendations of the Select Committee on Patent Medicines, the report of which was ordered by the House of Commons to be printed August 4th, 1914. This Committee proposed that fancy names for recognised drugs should be subject to regulation, and that the period of validity of a name used as a trade mark for a drug should be limited, as is already the case with patents and copyrights. We anticipate that legislation will follow in this direction.

## Annotations.

"No quid nlmis."

### THE FUTURE OF HOSPITALS IN IRELAND.

AN Irish correspondent writes: "There is no more urgent medical question in Ireland at present than the future of the voluntary hospitals. In Dublin, the Richmond, the Whitworth, and the Hardwicke Hospitals are controlled by a common board of governors, and since 1856 have enjoyed a Government subsidy of £7600 per annum. They have no other funds, and as the cost of maintenance has risen from a pre-war figure of £64 per bed to a present sum of £119 per bed, they are in serious plight. All the governors have tendered their resignation to the Lord-Lieutenant, the hospitals being now without funds to pay tradesmen's bills. The Whitworth Hospital is definitely closed. For some time the Treasury grant has been held by the bank and devoted to the reduction of the overdraft. The Irish Government has now expressed its inability to come to the relief of the hospitals in their present crisis, and if this course is persisted in the only chance is for the Dublin Corporation to act, but the rates are so terribly high in that city that little hope is felt in such a relief. In Belfast—with a population much larger than Dublin—the Government has never contributed a halfpenny to the hospitals, but it is plain that hospitals there cannot go on unless the working-classes themselves—with their present high wages—give more to the places to which their debt is so huge. At the Royal Victoria Hospital an arrangement is in force by which, for a penny a week contribution, a working man and his wife and family are treated at the hospital—as extern or intern patients—except for the zymotic fevers and tuberculosis. This plan, which was made about a quarter of a century ago, is utterly out of date now, and the contribution should be raised to at least sixpence weekly or even more. Middle-class people who formerly subscribed to the hospitals can do so no longer, as owing to the diminished purchasing value of the sovereign and the heavy taxation they are greatly crippled financially."

### THE COMMOTIONAL FACTOR IN THE ÆTIOLOGY OF SHELL SHOCK.

IN our present issue Dr. Alfred Carver records in some detail a series of experiments on animals which has a direct bearing on the problem of the ætiology and symptomatology of so-called shell shock. Dr. Carver describes in a lucid way the three zones produced round a point of detonation, and brings forward evidence to show the different physical effects in these three zones. In the first, the zone of "brisanee," objects are shattered by the sudden terrific compression; in the second, the zone of "decompression," there is very much less evidence of actual destruction or distortion of objects; in the third, outer zone, physical effects are modified still further. Some significance is attached to the fact that in the central zone other high explosives will, under the influence of the original detonation, themselves spontaneously detonate, as will, in the intermediate zone, those whose tonal standard is somewhat similar to that of the primary explosive. Corresponding to these physical changes are the effects produced on

animals finding themselves within the various zones; thus in the innermost zone animal life is destroyed, with laceration of the body structures; in the intermediate animals are rendered unconscious, often with no sign of external injury; in the outer a state of diminished activity is followed by a period of excitement and restlessness. Pathological evidence reveals numerous hæmorrhages in the zone A animals, and capillary engorgement in such zone B animals as are killed. There is, perhaps, something of the artificial and the schematic in these experiments, and some psychologists may be inclined to minimise their importance, as regards human beings, in judging of the effects of shell concussion not merely in the physical atmosphere but also in the mental. Dr. Carver's experiments, however, are supplemented by valuable observations on the effect of high-explosive detonations on a more or less picked set of men belonging to an "ammunition proof and demolition section," according to which definite physical and mental symptoms supervene on shell explosions even where the "psychic factor" can almost certainly be eliminated. Again, evidence is adduced of the peculiarly "demoralising" effect of shells with fillings layered in a special fashion, as though an unusual physical effect is somehow transformed into an unusual psychical disturbance. We feel that Dr. Carver is justified in his contention that both physical and psychical factors operate in the production of shell shock, and that differentiation of their respective actions is a matter of considerable difficulty. In any case, to ignore the physical element is unwise, and to restrict psychical phenomena to a psychical ætiology is unscientific. Our experience of shell-shock cases over the five years of war is in the main that the physical factor predominates in the originating of shell shock; that thereafter subconscious or unconscious "rumination" takes its place in the continuing of the symptoms; that the first two years saw more severe and protracted and inveterate cases of the condition than the last two—a fact which may be taken to suggest that in the perpetuation of symptoms the psychogenic element is much the more important. The *commotionné* becomes an *emotionné* in many instances; clear-cut examples of the two syndromes, we agree with Dr. Carver, are the exception and not the rule.

#### IMPERIAL CANCER RESEARCH FUND.

THE seventeenth annual report of this Fund, dealing with the year 1918-19, has just been issued, and consists of statements by the secretary, the director, and the honorary treasurer, together with a list of the year's subscriptions (£956 0s. 4d., making with amounts acknowledged in previous years £174,112 2s. 5d.), and a statement of accounts. Mr. F. G. Hallett, the secretary, points out that now it is becoming possible to resume systematic investigations in the laboratories the foresight shown by expending time and labour in maintaining the various tumour strains in mice is justified, for already material for research purposes has been supplied to Professor Borrel's Laboratory and the Institut Pasteur, Paris, and to Dr. J. Shaw Mackenzie at King's College. The report of the director, Dr. J. A. Murray, shows that during the war, while the working organisation has been maintained, the main efforts of the staff have been concentrated on war problems, the results of which work will shortly be published in the Sixth Scientific Report. This, for the most

part, will deal with the investigations of Messrs. W. E. Bullock and W. Cramer on new factors in bacterial infections, and by Dr. Murray on cellular changes on cartilage grafts. The report of Sir W. Watson Cheyne, the honorary treasurer, records the gratifying fact that the loan from the bankers has been reduced by £1700, leaving only £500 still to be cleared off. As the scientific staff, depleted owing to the war, is now nearly at full strength, researches will be energetically resumed with a necessarily increased expenditure, and an earnest appeal is made to all who are interested in cancer research to support the Fund themselves and to induce others to do likewise. "Looking to the heavy death-rate from malignant disease," says Sir Watson Cheyne, "it must surely be to the interest of the community that this Fund should not be starved in its efforts."

#### TRAUMATIC PSORIASIS.

FROM a recent article on this subject by Döllner,<sup>1</sup> of Duisburg, it appears that Köbner in 1872 was the first to describe this form of the disease. Another case was published in the *Lyon Médical* in 1895, in which psoriasis followed vaccination in a man, aged 22, who was alcoholic himself and belonged to an alcoholic family. Otherwise, apart from a case published by Becker in 1906, Döllner has not been able to find any example of traumatic psoriasis on record. He has lately observed two examples himself in soldiers who developed psoriasis after gunshot wounds, in one case of the tibia and fibula, where the psoriasis appeared on the injured leg but not at the site of the wound, and in the other at the actual site of the wound in the tibia. The last case was, further, of interest in that it proved to be infectious. Six months after his discharge from hospital the patient's wife, who had recently recovered from scarlet fever and still had a trace of albumin in the urine, developed psoriasis, which extended over both knees and the middle line of the back. In another two months her mother also contracted psoriasis. In a postscript Döllner relates the case of a stretcher-bearer who was wounded while carrying another wounded man, the subject of psoriasis, and developed the skin disease a fortnight later on his face, knees, and back.

#### THE PLIGHT OF VIENNA HOSPITALS.

THE prestige of the Vienna Medical School has for long been high in this country as anyone may see for himself by turning over the pages of the Medical Directory and noting the names of distinguished British surgeons and specialists who took post-graduate study there. The number of its students was never greater than was the case in 1914 on the eve of the war. The contrast between its situation then and the situation of the school to-day is startling and tragic. The hospitals, at first overwhelmed with wounded men and later with the victims of epidemic disease, are now filled with enfeebled and semi-starved patients, while lacking the food and equipment necessary to minister to their needs. Tuberculosis has developed into a deadly and acute disease. Nephritis has taken vast toll. Continuous underfeeding with its results seen as hunger-dropsy, rickets, scurvy, and Barlow's disease, provide the major part of the clinical material. In one clinic alone there were recently to be seen 18 cases of spontaneous fracture

<sup>1</sup> *Arzt. Sachverst. Ztg.*, 1919, xxv., 64-5.

in adults due to inanition. In consultation with Professor Tandler, Austrian Minister of Health, an effective organisation for the distribution of relief to the hospitals and kindred institutions has been brought into being. This is known as the International Spitalhilfsaktion, which has its offices at the Albrecht Palace, and its own private store houses. It is independent of other Government departments and is controlled by an international committee, of which Professor Wenckebach is chairman. An appeal to provide the urgent means of relief for this excellent organisation to distribute has been issued by Frau Dr. Biene, Frau Hofrath Lecher, Mr. C. K. Butler, chief of the British Mission, Mr. Halstead, chief of the American Mission, Mr. Karpeles, of Schenker and Co., and Dr. Hector Munro representing the Save the Children Fund. The most urgent need exists for extra rations to give to these hospital patients. The foodstuffs required are enumerated as fats (margarine, butter, cod-liver oil), sugar, eggs, meats, milk, and flour—the list suggesting, what we believe to be the fact, that the present diet of hospital inmates consists principally of broth and tea. 46,000 gallons of milk (of which 11,000 turned sour owing to difficulty of transport) are stated to have been the total supply for a population of over two millions during three recent days. Those to whom Vienna is a pleasant memory of student days will interest themselves in bringing the needs home to those who can supply them. The address of the Save the Children Fund is 329, High Holborn, London, W.C. 1.

#### TRAUMATIC ANEURYSM OF THE RIGHT VENTRICLE.

SPONTANEOUS aneurysm of the heart is rare enough; Dr. Claude Wilson, in recounting an interesting case, indicates how easily the condition may be overlooked. Traumatic cardiac aneurysm is rarer still, although less likely to elude diagnosis during life. In the *Journal of the American Medical Association* of June 7th Dr. G. H. Curfman and Dr. C. R. Fuller have recorded a case. On July 19th, 1917, a youth, aged 18 years, complained of the effects of a kick in the epigastrium by a mule. Since the injury he noticed difficulty in breathing, which steadily increased. There was persistent cough, accompanied by expectoration, the sputum consisting of frothy mucus tinged with bright blood. During the previous month the abdomen, ankles, and legs had become greatly enlarged. On examination the face was swollen, with marked puffiness under the eyes. The lips and tongue were very cyanotic. There was pronounced pulsation of the jugular veins. On lying down the whole face became extremely cyanotic. The cardiac impulse was heaving and could be seen to extend from the seventh interspace, about  $1\frac{1}{2}$  in. to the left of the middle line over the entire cardiac area. Cardiac dullness was greatly increased both to the right of the sternum and to the left of the mid-clavicular line. There was a loud systolic murmur most audible at the apex and transmitted over the whole cardiac area. At the end of systole the murmur became "whistling" and then faded into a faint blowing sound. The second pulmonic sound was accentuated. The abdomen was distended with fluid and there was marked tenderness, most noticeable in the epigastrium. The liver extended three fingers-breadth below the ribs and was tender on pressure. The lower limbs, from the ankles to above the knees, were swollen and œdematous. He gradually became worse; the cyanosis deepened and the abdomen became more distended with

fluid. The pulse became weak and irregular. On Feb. 27th, 1918, he passed into mumbling delirium and died. The necropsy revealed a greatly thickened pericardium containing about a litre of light amber-coloured fluid. The heart was enlarged and weighed 723 g. At the apex of the right ventricle was an irregular tumour about the size of half a lemon, which proved to be a sacculated aneurysm connected with the ventricle by an opening which admitted the index finger. The right ventricle was greatly hypertrophied and there was relative insufficiency of the tricuspid valve. The abdomen was normal except for a large amount of ascitic fluid.

#### THE HANDICAP OF DISABLEMENT.

THE Central Hall, Westminster, on July 24th was crowded from floor to ceiling with men who had lost their limbs in the Great War. The sight while the hall was being filled was one which at first could only engender feelings of despair, some of the men being so helpless that they had to be carried, others legless, shuffling along the floor by the aid of their arms only; but before the end of the meeting that feeling gave way to conviction that the awful pageant presented by the tragedy of war had its hopeful side. Under the auspices of the London War Pensions Committee and the British Red Cross Society the meeting was convened with the object of demonstrating to disabled soldiers and sailors the possibilities of success in life which lay before them, and with this purpose in view two American gentlemen, Judge Corley and Mr. Michael Dowling, who had been crippled in youth, but in spite of their disabilities had risen to positions of honour and trust, practically by their own efforts, gave their experiences. Sir Laming Worthington-Evans, Minister of Pensions, who presided, in introducing the speakers, said—and the attitude of the meeting proved his words—that if one really wanted to get among people who were stout-hearted and cheerful it was necessary to go among limbless men. He desired to see these men put in the service of the country, and into as good a position as possible by providing them with artificial limbs, but the coöperation of the men themselves was also necessary. Each man's case was a separate case, and after the skill of the surgeon, who was doing his very best, had been requisitioned, there was need for the individual who used the artificial limbs to select and learn to use properly the instrument which was best adapted to his purpose. Judge Corley, who had no arms, then gave a demonstration of the instrument which he had invented and perfected, and which enabled him to perform all the necessary actions of daily life. The main principle of the apparatus was that of the working of a pair of forceps, with various attachments for eating, drinking, performing the daily toilet, and even paring the toe-nails. As he explained, he could drive a motor-car, shave, play games—in fact, enter into life with the same enjoyment as a man with both his hands and feet. "And I get my full share of that enjoyment," he exclaimed with conviction. Warning his hearers against the danger of allowing the natural sympathy of the public towards them to lead to apathy, he concluded by exhorting the disabled to endeavour to do for themselves everything it was possible to do. Prince Albert, who was present, in the course of a short speech said: "We all know what you did in the war and what you have suffered, and it is now up to us to make

things as easy for you as possible. And only right that we should." The Prince then made an inspection of the exhibits of the work done by limbless men at the various training centres, which included many of the arts and trades of the country. After a cinematograph display showing Mr. Dowling as an expert motorist, the subject of the pictures himself gave a stirring address, the keynote of which was "grit." The knowing man, he said, did not pick out the winner by listening to the tales of tipsters or stableboys, but by noting the handicap and record of the horse. The greater the handicap the more certain it was that the horse had got the stuff in him if he won the race. And the man who had lost a limb in the war was likely to have the stuff to win. Mr. Dowling, who has lost both legs, half his left arm, and half his right hand, has risen in life from a state of poverty to that of president of the largest bank in Minnesota, and boasts that he can do everything in life except tie a bow-knot in his tie. In spite of his disabilities he won his bride against two whole-limb competitors, and is the father of healthy children.

#### PLAGUE AT LIVERPOOL AND AVONMOUTH.

THE Ministry of Health announces a fatal case of plague in Liverpool, in a bargeman. From the same source we learn that on the arrival of the s.s. *Framlington Court* at Avonmouth from Montreal on July 22nd, one of her officers, who was ill, was removed to the isolation hospital suffering from bubonic plague. Another officer, we are informed, having suspicious symptoms, was taken to hospital the following day and has been found also to be suffering from the disease. The vessel came from Alexandria to Montreal and called at Sydney, Nova Scotia, on her voyage to Avonmouth. She is being detained by the Bristol Port Sanitary Authority. All the accepted precautions have been taken, while the circumstances are being investigated.

#### GOVERNMENT SALARIES.

A VACANCY is announced for a medical inspector of factories who will be required to undertake medical inspection, under the direction of the senior medical inspector, in factories, workshops, and other places under the Factory Acts. The salary offered is £500 per annum, rising by annual increments of £20 to a maximum of £700 per annum, these figures being exclusive of war bonus; and the appointment is subject to the usual Civil Service regulations as to retirement and pension. The scale of salary will certainly be criticised at the present moment, when the salaries to be obtained in so many directions are considered, as well as the diminished and diminishing purchasing power of the sovereign. We may, however, remind intending candidates that the war bonus to be added to the salaries will be equivalent to an additional one-third, making, roughly speaking, the salaries nearly £700 and over £900 respectively. These, also, are not generous figures, but if the pay is maintained at that rate, and if proper account is given to the value of the pension, the salaries are not distinctly lower than those attached to many Civil Service appointments. It will, of course, be remembered that a war bonus is a distinctly conditional sum, and with a fall in prices might be arbitrarily withdrawn. We cannot attempt to estimate the

measure of this risk. But the Home Office must be served, and therefore it must pay salaries comparable to those paid by other departments. Having regard to the sums mentioned in connexion with posts in certain of the new bureaux, we feel that if the Home Office should later attempt to reduce the salaries which it is now offering it would be involved in a difficult struggle. Moreover, we should expect the salaries of medical inspectors of factories not to come down, but to go up in response to the increasing knowledge of the nation that on trade production depends our very life, while on healthy workers depends our trade production.

#### THE MENTAL NURSE'S WORKING DAY.

IN a recent number of THE LANCET (July 19th) we referred at some length to the conditions of asylum service in so far as these affected medical officers. The head of a large establishment dealing with one group of the mentally infirm calls our attention to another aspect of the matter—namely, that of the nursing of these patients. This question of mental nursing has been under consideration lately by the various authorities, with whom rests the responsibility of making suitable provision; and the two especially concerned with London, its County Council and the Metropolitan Asylums Board, have now adopted proposals for reducing considerably the hours of duty of the staff employed in their institutions. There is, of course, no parallel between ordinary industrial conditions and those of nursing, and many difficulties arise from the inability of certain workers to appreciate this fact. It is, therefore, not surprising that the two bodies just mentioned are experimenting on different lines, and it will be interesting to see which solution of the problem is found the more satisfactory. The County Council has adopted a three-shift system, each shift averaging eight hours on each of six days a week, while annual leave of 14 days is granted. In the institutions controlled by the Metropolitan Asylums Board the weekly total of hours worked is to be 50, spread over five days in each week, while four weeks of annual leave are to be given. The total number of hours on duty is the same under both arrangements—i.e., 2400 per annum. Both methods have their own drawbacks, and other schemes drawn up by other authorities are open to objections probably of equal weight. The chief requirements are to have a sufficient staff on duty at all times without having a superfluity at particular hours, and to provide that every ward shall have a responsible officer in charge of its equipment without its being necessary to check the stock twice a day or oftener as the change over is made. Since the working day, as distinct from the bedtime of the patients, must ordinarily extend over 14 hours—that is to say, 98 hours per week—it will be seen what a gap has to be filled when a charge nurse or attendant is only on duty for 48 or 50 hours. To keep patients in bed 12 hours out of the 24 is feasible in some instances, but can hardly be regarded as a good arrangement for young and active persons. Much will turn upon the spirit in which the staff take advantage of their extended freedom, but if the concessions made now are merely to serve as the basis for further demands the public practice of charity towards the weaker brethren is likely to prove an expensive luxury.

## PSYCHIATRY A HUNDRED YEARS AGO, WITH SOME COMMENTS ON THE PROBLEMS OF TO-DAY.<sup>1</sup>

BY BEDFORD PIERCE, M.D. LOND., F.R.C.P. LOND.,  
MEDICAL SUPERINTENDENT, THE RETREAT, YORK.

In the latter part of the reign of George III. many treatises on insanity were published, many of them possessing much literary grace. They abound in details of clinical cases, including frequently the appearance on post-mortem examination. Probably the public interest taken in the King's illness helped to stimulate this remarkable output. The volumes are full of interest, containing much that is wonderfully modern, yet it is not easy to enter into the spirit of the age, which was one of conflicting doctrines, old and new.

### *Blistering and Blood-letting.*

During the early part of this period medical treatment was based on the hypothesis that acute insanity was due to inflammation of the brain and its membranes; and it was considered necessary, by whatever method, to reduce the supply of blood to the brain. This can be illustrated by the treatment of George III. himself. It appears that his physicians were unanimous only on one occasion, when they decided to blister the King's legs to relieve his acute excitement! We are told that no beneficial result seemed to follow this operation.

Similarly, the practice of blood-letting was considered of great value. In 1811 Crowther, the surgeon to Bethlem, claimed to have bled 150 patients at one time, without untoward result. He also recommended emetics, quoting a case of hypochondriacal melancholia relieved entirely by their use. The patient took 61 vomits in the course of six months, and for 18 nights one every evening, yet made a perfect recovery! This view of the pathology of mania was supported by the post-mortem findings, which frequently described hæmorrhagic points in the substance of the brain.

### *The Treatment of Insanity.*

The treatment of insanity was founded on the anti-phlogistic theory, which at that time was generally held, and we must not pass hasty judgment on those who conscientiously accepted it. In our own times theoretical considerations have suggested methods of treatment that may be criticised adversely by our successors. For instance, since convalescents frequently possess an increased number of white blood-cells, it has been suggested that an artificial leucocytosis might promote recovery, and turpentine has been injected in order to produce an abscess. This line of treatment is founded on the gratuitous assumption that the leucocytosis in the two cases is similar in nature. The underlying thought is akin to that of Dr. Joseph Mason Cox, who recommended inoculation with small-pox, or the itch, and who said in his "Practical Observations on Insanity," published in 1804:—

"Certain it is that if any considerable commotion, any violent new action, can be excited in maniacal complaints, by whatever means, the mental derangement is often permanently improved."

This little book formulates the teachings of the whole school very concisely. It professes to state rules which will lead to "a more humane and successful method of cure," yet it offends the modern reader from start to finish. We are told that it is essential, in management, to procure the confidence of the patient, or to excite his fear. Pious frauds are recommended, and the case is recorded of a gentleman who imagined that his housekeeper had tried to murder him by means of poison in his shirts. It was arranged that she should be arrested, and dragged away in his presence; a bogus analysis of his shirts was made, which confirmed his suspicions; antidotes were prescribed, and he recovered in a few weeks.

Still more objectionable is the next method, which Cox strongly recommends—the use of a circular swing, invented by Dr. Erasmus Darwin, by means of which a patient, firmly strapped down on a chair or a bed, could be made to rotate round a central beam at any desired pace. It is only fair to

say that Cox gives most impressive instances of the marvellous cures accomplished, apparently, by the swing. It was recommended by many other physicians of experience, and in Morrison's lectures, published in 1828, an illustration of it was given, that every private asylum might be properly equipped.

The striking change in the treatment of the insane which began in the eighteenth century can be traced to three causes. First, there was the great humanitarian movement, which awakened sympathy with all human suffering; secondly, there was the gospel of liberty, equality, and fraternity preached in France, which penetrated even to the prison asylums of Paris; and, thirdly, there was a gradual enlightenment of medical opinion. So far as I can ascertain, actual priority in asylum reform belongs to Italy, where, between 1774 and 1778, Vincenzo Chiarugi, assisted by Daquin of Chambery, introduced new methods in Florence.

But the premier place in reform belongs to Philippe Pinel, who not only transformed the conditions at the Bicêtre and Salpêtrière in Paris, but convinced the world by his writings that the old methods were wrong and futile. His work on Mental Alienation, published in 1801, constituted a fresh departure. He was the hero of a wonderful chapter in the history of medicine, especially as his reforms were carried out during the darkest hours of the French Revolution. It was to the terrorist Couthon, who suspected him of harbouring aristocrats, that he made the remark which stands true for all time: "Citizens, I have a conviction that the insane are only intractable because they are deprived of air and liberty!" The same day he removed the chains from 50 of his patients.

### *"The Retreat," York.*

To pass to our own country, the Retreat, in York, was opened in 1796, long before Pinel's work was known here, through the united efforts of William Tuke and Lindley Murray, both members of the Society of Friends. The latter contributed much, in a quiet way, to the project; but the energetic, strong-minded William Tuke actually carried it through at the age of 60, and in spite of much misunderstanding and opposition. Even his wife is reported to have said, "Thou hast had many children of thy brain, William, but this last one will be an idiot!" In 1812 his grandson, Samuel Tuke, published "The Description of the Retreat," and Sydney Smith drew attention to it in a delightful essay, "Mad Quakers," which appeared in the *Edinburgh Review*.

The Retreat was fortunate in its first physician, Dr. Thomas Fowler, a man of keen scientific spirit, devoted to experimental research. He introduced the solution of arsenic known everywhere as Fowler's solution. He left in manuscript notes of 6000 cases, recited concisely and without bias, both failures and successes. Any drug or therapeutic agent which he investigated was administered singly, under conditions as similar as possible, but, to quote Tuke's description, he was "led to the painful conclusion, painful alike to our pride and to our humanity, that medicine as yet possesses very inadequate means to relieve the most grievous of human diseases." That conclusion, I fear, still holds good.

I should not like to convey the false impression that the Retreat was the only institution in England conducted on humane and enlightened principles; the report to the House of Commons in 1815 gives a very favourable account of Laverstock House, Salisbury, and Brislington House, Bristol. Both Pinel and Tuke stood for a complete change of outlook, involving not merely the abandonment of brutal methods of coercion, but the application of a new principle, which they called "moral treatment." By this they claimed that more could be done for the insane than by drugs and discipline. They asserted that the psychological environment of a patient was no less important than his physical condition.

### *Problems of To-day.*

To come to some of the problems that still vex us to-day. A hundred years ago only three sedative drugs were in use—opium, hemlock, and henbane, and opinion was greatly divided as to their value. Haslam strongly condemned opium, while Pinel suggested that experiments should be made in the use of various drugs, with proper attention to the specific distinctions of insanity. At present more than a hundred sedatives are advocated for sleeplessness or mental excitement, and the problem of their use is more complex than ever before. It is, of course, recognised that chemical

<sup>1</sup> Abstract of the Presidential Address to the annual meeting of the Medico-Psychological Association of Great Britain and Ireland, held in York, July 22nd, 1919.

restraint is generally hurtful, that drug habits are easily acquired, and that sedatives dull the faculties and mask symptoms. Moreover, all physicians in hospitals for the insane know that many newly admitted patients will not recover until the hypnotics given before admission are withheld. Yet, even now, we have no clear and satisfactory data. The extreme opinion of Haslam is shared by many present-day physicians. Prominent among these is Dr. C. K. Hitchcock, formerly the medical superintendent of Bootham Park, York, who, in 1900, published a striking article in the *Journal of Mental Science*, summarising the results of treating 206 cases of acute mania with no sedatives whatever. During the period in which he refrained from their use the rate of recovery was a high one.
